Re: Geotechnical Base Line Report
Carolina Crossroads
Richland/Lexington County, South Carolina
SCDOT Project ID P027662
F&ME File No. G5662.01

Dear Mr. Kinard:

Submitted herein is the geotechnical base line report for the above referenced project. Included is a summary of the subsurface data, the subsurface findings, the soil laboratory test results, and our preliminary evaluation for the conceptual bridge foundation systems and bridge/roadway embankments.

It has been a pleasure working with you on this project, and we appreciate the opportunity to be of service. Please notify us if there are any questions.

Respectfully Submitted,

EXECUTIVE SUMMARY

A limited geotechnical investigation was completed for the proposed Carolina Crossroads project. The geotechnical investigation was completed by two (2) geotechnical firms: F&ME and S&ME. The project is located just northeast of the City of Columbia, South Carolina. The geotechnical investigations were performed in general accordance with the Scope of Services and Schedule Contract Modification Number 2, dated January 11, 2018. The objective of the geotechnical investigations was to collect subsurface information and laboratory test data to be distributed to design-build teams for their use in pursuit of the construction contract. The project is planned to be procured though the SCDOT Design-Build process.

The following is a broad summary of the findings and our general interpretation of the subsurface conditions. This summary is presented for the convenience of the reader. The report text and data, provided herein, should be studied and understood before preparing any estimation of quantities or design.

1. As provided to F&ME by HDR, alternative RA1 was utilized to develop the geotechnical investigation plan. RA1 was included with several other alternatives in the NEPA submittal and was selected as the Recommended Preferred Alternative (RPA). The RPA concept primarily consists of adding capacity to Interstate 26, Interstate 20, Interstate 126, and the adjacent roadways by adding additional travel lanes and constructing new bridges. The RPA alternative consists of forty-six (46) new or replacement bridges and several retaining walls and sound walls. The RPA alignment was used as a reference on the boring locations plans and generalized subsurface profiles provided in the Appendix.
2. Two hundred nineteen (219) soil test borings, ten (10) cone penetrometer (CPT) soundings, and two (2) dilatometer soundings were performed along the proposed RPA alignment.
3. Six (6) major geologic units were identified: existing embankment fill, alluvium, Piedmont residuum, Coastal Plain soils, partially weathered rock, and bedrock.
4. The predominant rock type at the project is a fine-grained Phyllite, Schist, or Amphibolite. The fine-grained rock typically varies from moderately weathered to highly weathered and is considered weak to medium strong with unconfined compressive strengths generally less than 5,000 psi. At various depths within the rock mass, the fine-grained rock is considered extremely strong with a maximum recorded unconfined compressive strength of 70,000 psi. Granite was also encountered, but the location of the Granite is generally confined to the eastern extent of the project near the Saluda River. The Granite was classified as extremely strong rock with a maximum Unconfined Compressive strength of 40,000 psi.
5. F&ME and S&ME performed a qualitative geotechnical assessment for each bridge site proposed in the RPA alignment. The qualitative assessment consists of reviewing the boring logs, applying our experience on similar bridge projects, and developing conceptual foundation suggestions to assist the D-B Teams. No actual geotechnical analysis or design was performed during this phase of the project.
6. Six (6) downhole seismic borings were performed at select locations across the project. Subsurface shear wave velocity profiles were developed from the performed testing. This information was provided to SCDOT for development of the project's seismic design parameters. The seismic design information will be provided by SCDOT and is not included with this report.

7. Based on the results from the subsurface investigation and subsequent laboratory testing, most of the bridge embankments will likely meet the requirements of the SCDOT Geotechnical Design Manual (GDM) for the static and the seismic design events without ground improvement. At select sites where appreciable alluvium or Coastal Plain soils are present, the probability for ground improvement increases.
8. Driven pile foundations are considered the preferred bridge substructure element across the project. Driven piles will likely be used at bridge end bents but may also be used at bridge interior bent pile footings, retaining walls, sound walls, and overhead structures. We anticipate the Strength limit state will govern the geotechnical pile design at most sites. The driven pile foundations will develop the required axial resistance through skin friction in the residuum and/or end bearing on PWR/bedrock. Predrilling to advance the pile below the minimum tip elevation for lateral stability is expected at some locations.
9. Drilled shaft foundations will most likely be used for support of the bridge interior bents but may also be used in retaining walls, sound walls, and overhead structures. The Strength limit state axial loading conditions are expected to govern the geotechnical drilled shaft design. For the Strength limit state, drilled shaft foundations will develop the required axial resistance through skin resistance in residuum, PWR, and/or hard rock and/or end resistance in the PWR and hard rock.
10. Given the appropriate site and geotechnical conditions, shallow foundations are considered a viable foundation option for this project. The Structural and Geotechnical Engineers should coordinate their designs such that all performance criteria are met. Shallow foundations are considered most appropriate at new bridge locations where an existing embankment does not impact the design or where existing traffic will not be impacted by the foundation excavation requirements.

APPENDIX B F&ME Geotechnical Subsurface Data Report

APPENDIX C S&ME Geotechnical Subsurface Data Report

1. PROJECT DESCRIPTION

The project is located just northeast of the City of Columbia, South Carolina. A site location plan is presented in Section 1 of Appendix A.

The project will consist of widening Interstate 26, Interstate 126, and Interstate 20 near the intersection of Interstate 26 and Interstate 20. In addition, several existing overpass bridges are designated for replacement to facilitate the interstate widenings, and new bridge construction is planned to accommodate the proposed turbine interchange. In total, the project extends approximately nine (9) miles along I-26, two (2) miles along I-20, and just over one (1) mile on I-126. Based on the Recommended Preferred Alternative (RPA) alignment, a total of forty-six (46) bridges are planned for construction. Based on the conceptual drawings, the proposed bridge and roadway construction will mostly require fill placement, but there are locations where large cuts are required to meet the planned roadway grade. The cuts are mostly confined to the I-26/I-20 intersection. Furthermore, several retaining walls, sound walls, and overhead sign foundations are planned throughout the corridor. Each of these roadway structures contains a component that will require geotechnical design.

The geotechnical investigations were completed as a joint effort by F&ME and S&ME. The geotechnical field investigations were performed in accordance with the SCDOT Geotechnical Design Manual and the Scope of Services and Schedule Contract Modification Number 2, dated January 11, 2018.

2. SUBSURFACE INVESTIGATION

2.1. F&ME Subsurface Investigation

From January 3 to July 2, 2018, thirty-one (31) bridge soil test borings (designated as B-1 through B-28, B-6A, B-14A, and B-63), twenty (20) wall soil test borings (designated as W-1 through W-17, W-20, W-21, and W-26), thirty-five (35) roadway embankment soil test borings (designated as RW-1 through RW-34, and RW-28A), four (4) soil test borings for downhole seismic testing (designated as DH-1 through DH-3, and DH-3A), twenty-one (21) auger borings (designated as AP-1 through AP-21), and twenty (20) bulk soil samples were performed along the RPA corridor.

The soil test borings were advanced utilizing a CME 550 ATV mounted drill rig and a CME 45B trailer mounted drill rig. Rotary wash drilling techniques were used to maintain a stable borehole. Standard Penetration Tests (SPT) tests were continuously obtained in the top ten (10) feet of each test boring. Following the continuous sampling, SPT samples were obtained at regular, five (5) foot intervals throughout the remaining depths of the borings. SPT samples were performed in general accordance with ASTM D-1586 to determine the relative densities and consistencies of the subsurface soils and to collect subsurface soil samples. An automatic hammer was used to perform the borings. The measured energy ratio for the CME 550 hammer is 81%. The measured energy ratio for the CME 45B hammer is 84%.

The bridge borings and wall borings were advanced to either a target depth or tri-cone roller bit drilling refusal, whichever was shallower. Where a drilling refusal condition was encountered, the borings were subsequently advanced into rock using NQ sized rock coring equipment. The roadway embankment borings were advanced to either a target depth or tri-cone roller bit drilling refusal, whichever was shallower, and were subsequently terminated. The downhole seismic borings were advanced to a minimum depth of approximately 120 feet to facilitate the geophysical testing in the upper 100 feet. Within the seismic borings and where a drilling refusal condition was encountered, the borings were subsequently advanced into rock using NQ sized rock coring equipment to the minimum depth. DH-3 was terminated near the ground surface on an apparent shallow boulder. DH-3A was offset approximately five (5) feet from DH-3 and did not encounter shallow refusal.

The auger borings were performed for the primary purpose of collecting intact, Shelby Tube samples. SPT testing was not performed within the auger borings. The auger borings were advanced to target depths and subsequently terminated.

The bulk soil samples were collected for laboratory testing to provide soil strength parameters for the existing embankment soils or soil strength parameters in areas designated for excavation. The bulk soil samples were collected and composited from borings to an approximate depth of five (5) feet to ten (10) feet below the existing ground surface and subsequently terminated.

2.2. S&ME Subsurface Investigation

From January 4 to June 6, 2018, thirty-five (35) bridge soil test borings (designated as B-29 through B-62, and B-36A), twelve (12) wall soil test borings (designated as W-18, W-19, W-22 through W-25, and W-27 through W-32), nine (9) roadway embankment soil test borings (designated as RW-35 through RW-43), seventy (70) pavement soil test borings (designated as P-1 through P-71), three (3) soil test borings for downhole seismic testing (designated as DH-4 through DH-6), eight (8) auger borings, and thirty (30) bulk soil samples were performed along the RPA alignment.

The soil test borings were advanced utilizing a Diedrich D-50 ATV mounted drill rig, a CME 55 truck mounted drill rig, and a CME 750 ATV mounted drill rig. Bridge, retaining wall, embankment, and seismic borings were advanced using rotary wash drilling techniques. The pavement borings utilized hollow stem auger drilling techniques to maintain a stable borehole. Standard Penetration Tests (SPT) tests were continuously obtained in the top ten (10) feet of each test boring. Following the continuous sampling, SPT samples were obtained at regular, five (5) foot intervals throughout the remaining depths of the borings. SPT samples were performed in general accordance with ASTM D-1586 to determine the relative densities and consistencies of the subsurface soils and to collect subsurface soil samples. An automatic hammer was used to perform the SPTs. The measured energy ratio for the Diedrich D-50 hammer is 87%. The measured energy ratio for the CME 55 hammer is 84%. The measured energy ratio for the CME 750 hammer is 86%.

The bridge borings and wall borings were advanced to either a target depth or tri-cone roller bit drilling refusal, whichever was shallower. Where a drilling refusal condition was encountered, the borings were subsequently advanced into rock using NQ sized rock coring equipment. The roadway embankment borings were advanced to either a target depth or tri-cone roller bit drilling refusal, whichever was shallower, and were subsequently terminated. The pavement borings extended to a target depth of approximately ten (10) feet and were subsequently terminated. The downhole seismic borings were advanced to a minimum depth of 120 feet to facilitate the geophysical testing in the upper 100 feet. Within the seismic borings and where a drilling refusal condition was encountered, the borings were subsequently advanced into rock using HQ sized rock coring equipment to the minimum depth.

The auger borings were performed for the primary purpose of collecting intact, Shelby Tube samples. The auger borings were advanced to target depths and subsequently terminated.

The bulk soil samples were collected for laboratory testing to provide soil strength parameters for the existing embankment soils or soil strength parameters in areas designated for excavation. The bulk soil samples were collected and composited from borings to an approximate depth of ten (10) feet below the existing ground surface and subsequently terminated.

2.3. Geotechnical Investigation Summary

In total, 219 soil test borings were performed along the project: 66 bridge borings, 32 wall borings, 44 roadway embankment borings, 7 downhole seismic borings, and 71 pavement borings. In addition, 50 bulk soil samples were collected, and 41 auger borings were performed along the project corridor. The geotechnical investigation performed by F&ME and S&ME during this phase of the project is summarized in Section 2 of Appendix A.

We have provided Boring Location Plans in Section 3 of Appendix A. The boring location plans display the locations of the borings performed by both F&ME and S&ME during the subsurface investigation(s). A summary of the lithology symbols shown on the subsurface profiles and the boring nomenclature used by F&ME and S&ME for this project are provided before the profiles in Section 4 of Appendix A. Individual boring logs are provided in Appendix B and Appendix C.

3. LABORATORY TESTING PROGRAM

Select soil samples from the borings were tested in either F&ME's or S&ME's AASHTO certified laboratory to determine physical and engineering soil properties. These tests were used to identify the strength and behavioral characteristics of the soils as well as to verify the field classifications by the AASHTO classification system and the Unified Soil Classification System (USCS). The laboratory testing program is summarized in the following table. These quantities represent tests performed by both F&ME and S&ME.

Laboratory Testing Table	
Test Type	Quantity
Moisture Content	607
Grain Size w/ Wash #200	621
Atterberg Limits	616
CU Triaxial	40
UU Triaxial	2
Consolidation	8
Unconfined Compression - Rock	124
Standard Proctor	50
Electro-Chemical Series	60
Ignition Loss	13
Organic Content	9
California Bearing Ratio	21

All soil testing was conducted in general accordance with applicable ASTM/AASHTO standards. Data sheets presenting the results of F&ME's laboratory test program are provided in Appendix B. Data sheets presenting the results of S&ME's laboratory test program are provided in Appendix C.

4. REGIONAL SITE GEOLOGY

The project is situated mostly in the Piedmont Physiographic Province at the South Carolina Fall Line zone. More specifically, the site is located within the Carolina Terrane (formerly referred to as the Carolina Slate Belt). The Piedmont unit is characterized by gently rolling topography, weathered bedrock, and few hard rock outcrops. The site subsurface conditions generally consist of existing embankment fill, residual soils, alluvial soils, Coastal Plain soils, partially weathered rock (PWR), and bedrock. Being so close to the Fall Line, the degree of weathering of the bedrock is highly variable, and the depth to sound, unweathered bedrock varies greatly across the project area.

At the Saluda River crossings along the I-126 corridor and at Stoop Creek near the St. Andrews Rd. over I-26 intersection, Quaternary, alluvial soils were encountered below the existing embankment fill. Due to their recent deposition, the relative densities of this material will be lower and their proximity to the water could potentially lend them to problems relative to seismic quaking. In general, SPT N-values suggest loose to medium dense sands and soft to firm silts and clays. Residual soils were encountered below the alluvium, where present.

In general, coastal plain soils were encountered north of the I-26/I-20 interchange and gradually terminates just southwest of the interchange. The extent of the coastal plain material generally follows the limits shown on the publicly available geologic mapping (SCDNR 1972). These soils are considered Cretaceous-aged. The relative densities of this material will be lower compared to the underlying residuum and their proximity to the water could potentially lend them to problems relative to seismic quaking. In general, SPT N-values suggest loose to medium dense sands and firm to stiff clays. Residual soils were encountered below the coastal plain soils, where present.

The encountered Piedmont residuum generally consists of varying amounts of sand and silt. The thickness of the residual soils will vary across the project. At some locations, the residuum was on the order of ten (10) feet thick, and at other locations the thickness was on the order of fifty (50) feet. In general, SPT N-values suggest medium dense to dense sands and very stiff to hard silts.

Below the residual soils, partially weathered rock (PWR) was typically encountered. PWR is an intermediate geo-material (IGM) that is experiencing a transition from the parent bedrock to weathered in-place, residuum. By definition, PWR is a soil exhibiting SPT N-values in excess of one hundred (100) blows per foot (bpf). Moving away from the Fall Line, the PWR is thinner and is on the order of ten (10) to twenty (20) feet thick. At the I-20/I-26 intersection, the PWR thickness is greater than 100 feet thick. Borings were terminated in PWR at depths of 120 feet without encountering hard bedrock. PWR will likely be the primary bearing stratum for driven piles foundations and/or drilled shaft foundations at most bridge sites.

Below the PWR, bedrock was encountered. Rocks of the Carolina Terrane typically consist of metamorphosed volcanic and sedimentary rocks. The rocks encountered along this project consist of Phyllite, Schist, and Amphibolite. The Phyllite/Schist/Amphibolite extends from the west to the east and generally dips below a hard granite pluton as it moves east near the Saluda River. Granitic bedrock associated with the aforementioned pluton was encountered at boring locations along I-126 and in the vicinity of the I-26 bridge over the Saluda River that is generally consistent with the published geologic mapping (SCDNR 1972).

5. SUBSURFACE CONDITIONS

5.1. Soil Stratigraphy

The soil borings indicate six (6) main strata underlying the project. The following table provides a very generalized summary of the encountered soils across the project. Due to the lateral extent and variable topography of the project, depths and elevations of the stratigraphy may vary greatly. Refer to the boring location plans and the individual boring logs for more accurate subsurface information at a particular location.

Soil Stratification Table

Geologic Formation	Approx. Layer Thickness (ft)	USCS Soil Type	AASHTO Soil Classification	Avg. SPT N-Value (bpf)	Average CPT Tip Resistance (tsf)	Comments
Existing Embankment Fill	2-30	SM/ML/ CL/CH/SC	A-2-4/ A-2-6/ A-4/A-6/A-7	13	41	
Alluvium	0-30	GC/SM/SC/ ML/MH/CL/ CH	A-1/A-2-4/ A-2-6/A-4/ A-5/A-6/A-7	14	46	@ bridges over Saluda River, I-126, and @ Stoop Creek near St. Andrews Rd.
Coastal Plain (Pleistocene)	0-40	SM/SC/SP/ MH/CL/CH	A-2-4/A-2-6/ A-3/A-5/ A-6/A-7	15	52	Generally north of I-26/ I-20 intersection
Residuum	5-80	SM/ML	A-2-4/A-4	33	42	
PWR	10-100+	SM/ML	A-2-4/A-4	100+	N/A	
Bedrock	--	--	--	--	--	See Section 5.2

5.2. Rock Conditions

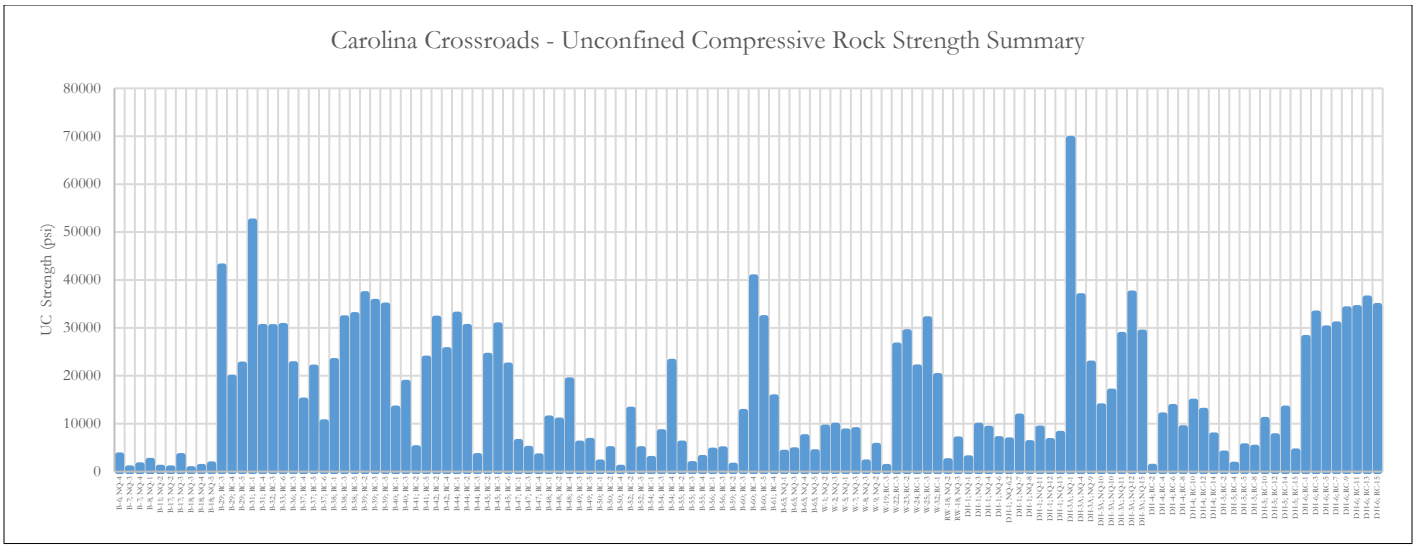
Following auger refusal conditions encountered in the test borings, rock coring operations were conducted. The core depths vary from ten (10) feet to eighty (80) feet. The greater core depths are at the downhole seismic borings for acquiring subsurface shear wave velocity data to a depth of 100+ feet. F&ME utilized diamond NQ rock coring techniques to recover the rock core samples in general accordance with ASTM D2113. S&ME utilized diamond NQ rock coring techniques in borings other than the downhole seismic borings in general accordance with ASTM D2113. For the downhole seismic borings, S&ME utilized HQ sized rock coring equipment.

At a majority of the boring locations, the rock type is fine-grained and is generally classified as phyllite, schist, or amphibolite. Towards the eastern extent of the project near the Saluda River, the rock is classified as extremely strong (ie. > 30,000 psi) granite. The fine-grained rock is classified as weak to medium-strong and highly weathered to moderately weathered. The in-situ rock has numerous, wide joints. At many locations, the joints are nearly vertical, and the geotechnical drilling was slow and difficult. The core recovery (REC) ranges from zero percent (0%) to one hundred percent (100%), and the rock-quality designation (RQD) for the lengths

recovered ranges from zero percent (0%) to one hundred percent (100%). UC strengths of the intact fine-grained rock samples generally range from 500 to greater than 30,000 pounds per square inch (psi) with a maximum recorded strength of almost 70,000 psi. Several of the UC strength tests indicate a shear failure along a visually discernable bedding plane. As such, the indicated UC rock strengths may not be representative of the actual rock strength. Further in-situ or laboratory testing may be employed to investigate this condition.

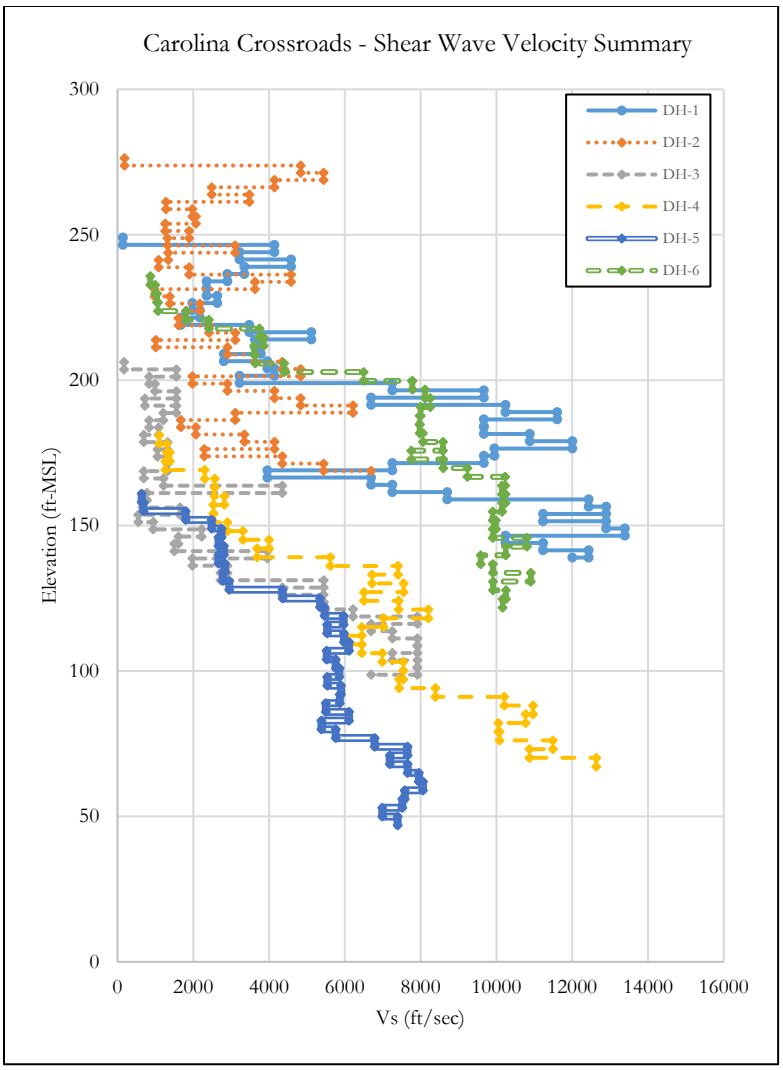
The granite is classified as very strong to extremely strong and highly weathered to fresh. The in-situ rock has numerous, very tight joints. Joints are dipping at low to high angles (0 to 90 degrees) with a majority of the joints dipping between 0 and 50 degrees. The core recovery (REC) ranges from six percent (6%) to one hundred percent (100%), and the rock-quality designation (RQD) for the lengths recovered ranges from zero percent (0%) to one hundred percent (100%). UC strengths of the intact rock samples generally range from 3,000 to greater than 30,000 psi.

A summary of the rock core compressive strength testing is provided in Appendix B and Appendix C. A graphical summary of all of the rock strengths performed by F&ME and S&ME is provided in the chart below.



5.3. Subsurface Shear Wave Velocity

Six (6) downhole seismic borings were performed along the project. The shear wave velocity measurements recorded within these boreholes are summarized in the following chart.



The shear wave velocity information was submitted to SCDOT for development of the project seismic design data.

5.4. Groundwater Conditions

Groundwater table measurements were recorded immediately following completion of the borings and/or 24-hours following completion of the borings. The depth to the groundwater table is highly variable across the project. The depth to the groundwater table ranged from approximately one (1) to fifty (50) feet. Groundwater elevations along this project will fluctuate with climactic events. During and following periods of rainfall, the water table may be encountered at higher elevations than identified on the field testing logs. In addition, the project is conducive to perched groundwater conditions. We would expect that water from recent rainfall would sit atop the denser, fine-grained residuum. Perched groundwater is not indicative of the true, static groundwater table. The Design-Build team should evaluate the groundwater conditions at discrete locations and exercise engineering judgement to assign an appropriate groundwater table for design purposes.

6. CONCEPTUAL GEOTECHNICAL ASSESSMENT

The geotechnical information, provided herein, is conceptual and is based on limited geotechnical data. The information provided should be supplemented and evaluated relative to the SCDOT GDM and Team specific design and construction requirements for preliminary and final design purposes. Following the collection of additional subsurface data, these recommendations may change or become invalid. For each bridge site, we have provided very general and conceptual geotechnical information based on the subsurface information collected by F&ME and S&ME during this phase of the project. The conceptual bridge foundation information is provided in tabular form in Section 6 of Appendix A.

6.1. Site Preparation

Based on the subsurface conditions encountered during the field investigations, the soil subgrade below the planned embankment areas appear to be adequate for embankment construction. The embankment subgrade soils may contain appreciable silt and mica content that, when wet, would perform unsatisfactorily. The shear strength of these soils tends to deteriorate during wet conditions as they are re-worked by construction equipment. For this condition, localized mucking, bridge lifts, and/or soil reinforcement may be required to achieve acceptable performance for normal, static conditions. During and following periods of rainfall, mucking operations may be more prevalent. Depending on the locations and composition of the subgrade soils, mucking may be minimized if the soils are allowed to dry.

Earthwork excavation will be required to meet the proposed roadway grade at select locations based on the D-B Team's roadway design. These excavations could encounter hard soils or rock near the ground surface that may require non-typical earthwork construction equipment. In general, shallow rock was encountered at locations near the western extent of the project along I-26. Shallow rock and/or PWR may be encountered at other locations throughout the project that were not explored during the investigations that were performed under this scope of work. In addition, boulders of varying sizes may be encountered in the existing embankments. We anticipate that the presence of boulders increases moving towards the eastern extent of the project along I-26.

At locations across the project, cut sections are indicated on the concept plans to meet the planned roadway grades. At these locations, there may be appreciable mica content in these soils. Mica in soils can affect the engineering properties of the soil, especially the compaction properties. The Design-Build team should carefully evaluate the soils in the locations designated for excavation if these soils are planned to be reused as fill in new embankment construction.

Earthwork activities will impact a variety of other construction elements associated with the project. The cut/fill and the depth to rock/PWR relative to the cut/fill depths should be addressed for, at a minimum, new and existing pipe culverts, new and existing box culverts, jack-and-bore installations, and temporary shoring. If existing pipe or box culverts are expected to support additional loading from fill placement or increased live loading from reduced cover, the culverts should be structurally and geotechnically evaluated for the additional loading.

6.2. Buried Elements

During previous vintages of highway construction along this corridor, a variety of buried elements have been discovered or are known to exist. These elements consist of boulders, construction and demolition waste, etc. Specifically, we understand that the previous Piney Grove Rd. bridge debris is buried in the vicinity of the I-26 EB off-ramp. We have identified several locations where buried structures exist that may impact roadway and/or bridge construction. We have not attempted to identify all the buried elements along the project, and the Contractor should be prepared to deal with buried elements when performing earthwork activities along the corridor.

6.3. Geotechnical Seismic Hazard Potential

Geotechnical seismic hazards consist of a loss in a soil's shear strength through cyclic ground motions induced by earthquakes. In sand-like soils, this phenomenon is typically referred to as soil liquefaction. Cyclic-softening is the typical terminology for fine grained soils. Liquefaction of sand-like soils is considered the most devastating seismically induced geotechnical hazard.

Liquefaction is the loss of a soil's shear strength due to a rapid increase in pore water pressure resulting from soil particle contraction induced by seismic vibrations. Soils most susceptible to liquefaction generally consist of saturated, loose, "clean" (i.e., Plasticity Indexes less than 7), fine (10% particle size ranging from 0.07 millimeters to 0.25 millimeters) sands. Soil softening occurs in moderate to high plasticity silts and clays.

Based on a qualitative review of the collected subsurface information, seismic Soil Strength Loss (SSL) is not expected for most of the sites across the project. Localized pockets of material susceptible to SSL may be encountered at the sites where alluvium and Coastal Plain soils were encountered. In general, structures near St. Andrews Rd., Broad River Rd., and the Saluda River, may have soils that are susceptible to SSL. Depending on the location of these soils relative to the existing and final grades, ground improvement may be required to meet acceptable performance during and following the design seismic event.

6.4. Seismic Induced Settlement

At locations where SSL triggering may be present, a seismic deformation analysis should be performed to calculate the vertical settlement from the sand-like soil particle re-distribution. In addition, the lateral displacements should also be calculated from lateral spreading of the liquefied soils and their impact on foundations should be addressed.

Following the acquisition of additional subsurface information, the Design-Build Team should carefully evaluate the liquefaction potential at each site and determine if ground improvement is necessary to accommodate seismically induced settlement. The potential for seismically induced settlements appears to be low across the majority of the project. However, structures near St. Andrews Rd., Broad River Rd., and the Saluda River may have soils that are susceptible to seismically induced settlement.

6.5. Static Settlement

In general, the proposed bridge and roadway embankment subgrade soils consist of moderate density/consistency sand and silt above the static, groundwater table. Fill placement along the project will result in deformation of the subgrade soils. We anticipate that any problematic soils near the ground surface, would be removed and replaced prior to fill placement, since these soils would be difficult to stabilize prior to embankment construction. We anticipate that a majority of the settlement across the project would occur rapidly with fill placement. The potential for extensive, long-term consolidation settlements appears to be low across the project. We did not identify a specific geographic location across the project where appreciable long-term settlements would be an issue.

6.6. Embankment Slope Stability

Static and seismic stability analyses are required at the bridge embankments and the retaining wall locations regardless of the Roadway Operational Classification (ROC). Only static stability analyses are required at the ROC IV roadway embankment locations. From reviewing the boring logs, we anticipate that most of the static and seismic slope stability analyses will yield resistance factors that meet the GDM criteria without ground improvement. In certain locations, soil reinforcement may be necessary to achieve the desired resistance factor. In general, embankments and walls near the Saluda River and Broad River Rd. may present challenging global stability soil conditions.

6.7. Ground Improvement

In general, the potential for ground improvement for this project appears to be low. At various bridge embankment and retaining wall locations, ground improvement to mitigate seismic instability and/or excessive seismic deformations may be required. If ground improvement is required to achieve acceptable seismic performance, we would anticipate that it would be limited to those structures with appreciable coastal plain and alluvial soils below the ground water table. In general, these locations are expected to be mostly confined to bridges and/or walls near the Saluda River and Broad River Rd. We anticipate that the ground improvement would target increasing shear strength as opposed to mitigating settlement. These types of ground improvements would include, but are not limited to, geogrid, geotextile, and discrete elements that would densify, add strength, and/or improve drainage. Deeper, in-situ ground improvements such as stone columns and deep soil mixing may require penetration into hard soil and/or rock and would likely present constructability issues.

6.8. Foundation Corrosion and Deterioration

Per AASHTO, the following soil or site conditions are considered indicative of a potential for steel corrosion and/or concrete deterioration.

- Resistivity less than 2,000 ohm-cm;
- pH less than 5.5;
- pH between 5.5 and 8.5 in soils with high organic content;
- Sulfate concentrations greater than 1,000 ppm;
- Landfills and cinder fills;
- Soils subject to mine or industrial discharge; and,
- Areas with a mixture of high resistivity soils and low resistivity high alkaline soils.

Per AASHTO, the following water conditions are considered indicative of a potential for steel corrosion and/or concrete deterioration.

- Chloride content greater than 500 ppm;
- Sulfate concentration greater than 500 ppm;
- Mine or industrial runoff;
- High organic content;
- pH less than 5.5;
- Marine borers; and,
- Piles exposed to wet/dry cycles.

Electrochemical testing was performed on select soils collected along the project corridor. Electrochemical test results are provided in Appendix B and Appendix C. Based on the pH test results, the potential for steel corrosion is indicated to be moderate across the project. Several of the test results indicated pH levels less than 5.5. Sulfate levels were generally less than the allowable limits, and the potential for subsurface concrete degradation is indicated to be low. Following additional subsurface testing, the D-B team should carefully evaluate the geotechnical conditions relative to corrosion and degradation and provide mitigation measures, as necessary.

6.9. Pile Foundations

Pile foundations are anticipated for support of the bridge end bents and may be used for support of bridge interior bents depending on the site geometry and subsurface conditions. Pile foundations may also be used to support retaining walls, sound walls, and overhead signs. Driven pile installations would be preferred, and we anticipate that most locations can utilize driven pile techniques. Some locations may require pre-drilling in order to meet the minimum pile tip elevations for lateral stability. The potential for predrilling is higher along I-26, west of St. Andrews Rd. In general, pile foundations are considered preferable for the anticipated construction. Specific pile foundation design issues are discussed in the following sections.

6.9.1. Axial Resistance

The Strength limit state axial loading conditions are likely to govern the geotechnical pile designs at most of the bridge sites.

Driven piles will develop a majority of the required driving resistance through end bearing on PWR or bedrock. We expect that medium to large pile hammers will be required to advance piles through the denser residuum to the bearing stratum. For a majority of the pile installations, the pile driving termination criteria may consist of driving the piles to a refusal condition. The Contractor should exercise care to not over-drive, over-stress, and damage piles on an impenetrable bearing stratum.

If the pile tip elevations are placed above a location where a pile driving practical refusal condition exists, then the D-B Contractor may elect to perform Pile Dynamic Analyses (PDA) testing with CAPWAP measurements to monitor pile driving stresses during driving and to verify the in-place, driven pile resistance. If the required driving resistance is not attained during initial drive, then a wait period may be implemented to allow for pile freeze. Following the wait period, pile driving re-strikes should be performed. Continuous PDA testing should be considered during both the initial drive and the re-strikes, as necessary. The number of required PDA tests shall be in accordance with the GDM.

6.9.2. Lateral Resistance

For the Strength limit state, Service limit state, and the Extreme Event limit state, we anticipate that the driven piles will develop the required lateral stability in the existing embankment fill and the upper residual, alluvial, or coastal plain soils. SSL should be evaluated to determine if foundations should be extended below the depths needed to satisfy the Strength and Service limit states. At the end bents, the seismic bridge abutment backwall passive pressure shall be calculated in accordance with Chapter 14 of the GDM for the existing embankment fill material or the selected embankment fill material.

6.9.3. Drivability

Driven piles will likely use a diesel pile hammer. We anticipate that non-displacement piles (ie. steel H-piles or steel open-ended pipe piles) will be utilized at the end bents and may be utilized at interior bents depending on the site geometry and subsurface conditions. The anticipated pile length for non-displacement piles could vary from ten (10) feet to ninety (90) feet across the project. Pre-stressed concrete (PSC) piles may be used where appreciable alluvium and/or coastal plain soils are present. We do not expect the subsurface conditions at most sites along the project would be conducive to PSC piling.

Based primarily on experience, large boulders may exist in the alluvial soils and near the Saluda River. In addition, some boulders may exist in the existing embankments from previous vintages of road construction. We anticipate that shallow rock or boulders may have been removed under the travel lanes at the time of construction, disposed of in the existing embankment side slopes, and covered with fill material. During our field investigation, only a few boreholes encountered material that was considered a potential boulder, but we expect that more boulders would exist than is indicated in the provided test borings. The probability of encountering boulders increases moving east along I-26, towards Columbia. If boulders are discovered during pile installations, predrilling and/or rock coring may be required to bypass the impenetrable layer and achieve pile lateral stability.

Based on the anticipated pile lengths, we expect that most steel pile foundations will require a pile splice and will be driven in two (2) sequences. When pile driving in the dense residuum and when pile tip elevations are above the minimum tip elevations, the Contractor should be careful to minimize the time between sequences to avoid substantial pile freeze such that the piles cannot be further advanced to a minimum tip elevation requirement. We anticipate that a medium/large pile hammer will be required to advance the piles through the dense residuum to the bearing stratum. We expect that most piles will be driven to a practical refusal condition on PWR or bedrock. The Contractor should exercise care to not over-drive, over-stress, and damage piles on an impenetrable bearing stratum after encountering a practical refusal condition. Assuming that pile installations will terminate on a practical refusal condition and due to the proximity of commercial and residential structures relative to the proposed construction, the Contractor should develop a strategy to manage and limit the generated earth-borne vibrations from pile installations.

For a properly selected driving system, we do not anticipate unusual pile driving issues for successful installation of the driven piles. The selected driving system shall address driving compressive and tensile stresses to conform to the SCDOT criteria.

6.10. Drilled Shaft Foundations

We anticipate that drilled shaft foundations would primarily be used at the bridge interior bents. Drilled shafts may also be used for support of retaining walls, sounds walls, and overhead signs. We anticipate that drilled shaft sizes could range from 36 inch to 84 inch diameter shafts. Specific drilled shaft design issues are discussed in the following sections.

6.10.1. Axial Resistance

The Strength limit state axial loading conditions are expected to govern the geotechnical design of drilled shafts.

Depending on the approach taken by the Design-Build team, we expect that a majority of the drilled shafts will develop the required axial resistance through skin friction in the residuum, IGM and bedrock and/or through end bearing on PWR or bedrock. Since drilled shafts mobilize shaft resistance and end resistance at different displacements, it is difficult to predict the load transfer from skin resistance to tip resistance. The Design-Build Team should exercise caution when using a drilled shaft design including both skin friction and end bearing in PWR and rock.

Construction casing will be required to facilitate drilled shaft construction. It is anticipated that the casing would either be socketed in stable, residual soils or advanced to the top of PWR or bedrock. We anticipate that casing lengths would be on the order of ten (10) to forty (40) feet long. The drilled shaft design methodology does not allow for resistance development in the cased portion of the drilled shaft. As such, the drilled shaft design will generate the required resistance in the uncased portion below the casing tip elevation. The anticipated drilled shaft lengths below the casing tip elevations may range from ten (10) feet to eighty (80) feet.

6.10.2. Lateral Resistance

For the Strength limit state and Extreme Event I limit state, the drilled shafts will develop most of the required lateral stability in dense residuum, PWR, and/or rock. Most sites do not cross waterways and are not impacted by scour, but the bridges over the Saluda River will likely scour to PWR or rock. The lateral resistance will be developed below the scour elevation. At the river crossings where the rock is extremely strong, the geotechnical drilled shaft design may be governed by lateral stability requirements. At other locations, we expect the axial loading condition will govern the geotechnical design.

6.10.3. Constructability

Drilled shaft construction will likely require excavation of hard soil (SPT N-values in excess of 100 bpf) or rock. In general, the measured rock strengths along the project suggest weak to extremely strong rock conditions. The extremely strong rock conditions are generally confined to the eastern extent of the project near the Saluda River. Rock strengths at these locations may exceed 30,000 psi with maximum measured values of 70,000 psi and will be difficult and time-consuming to excavate. In addition, the softer, fine-grained rock has nearly vertical joints at several locations. The vertical jointing will affect the Contractor's drilling advancement rate. The Contractor should be prepared to deal with jointed and

fractured rock in their drilled shaft installation plan. Specialized drilling equipment may be required to excavate through the PWR and into the bedrock. This may include, but not be limited to, rock augers, core barrels, or pneumatic equipment. The Contractor should be prepared to provide equipment capable of drilling through rock with compressive strengths on the order of 70,000 psi.

Drilled shaft excavations in PWR may require other equipment beyond a standard soil auger. In addition, drilling in this material without a mineral slurry may result in sloughing of the sides of the excavation. The sloughed material may fall to the bottom of the excavation, and, if not properly cleaned prior to concreting, may result in defects at the bottom of the drilled shaft.

6.11. Shallow Foundations

Shallow foundations are not typically utilized on SCDOT bridges due to the difficulty with balancing both settlement and bearing capacity requirements. At select locations where the site geometry and the soils conditions allow, shallow foundations may be suitable as a bridge substructure element. Shallow foundations may be desired for support of retaining walls but may also be used for sound walls and overhead signs if the conditions allow. Specific shallow foundation design issues are discussed in the following sections.

6.11.1. Bearing Capacity and Settlement

Where hard residuum, PWR, or bedrock is shallow and where the groundwater table is below the bearing elevation, shallow foundations may be an appropriate foundation option for bridges, walls, and/or signs. If SSL and/or soft soils are present below the proposed bottom of footing elevation and if shallow groundwater is present above the proposed bottom of footing elevation, then shallow foundations should not be considered. The Structural Engineer and Geotechnical Engineer should coordinate their designs such that all performance criteria are met.

6.11.2. Constructability

The ability to utilize shallow foundations may be limited by the site geometry. For example, shallow foundations will likely not be appropriate for the bridges over the interstates due to the proximity of existing traffic relative to the available space in the median. The footings would likely need to extend below the interstate pavement section. Depending on the construction sequencing and maintenance of traffic concept, temporary shoring may be implemented to facilitate the shallow foundation construction. We anticipate that shallow foundations would be suitable at the new bridge sites where an existing embankment does not impact the design and where construction would not need to accommodate existing traffic. Open excavations, without the use of temporary shoring, may be allowed to provide clearing for the proposed shallow foundation geometry and to access the bearing elevation. The shallow foundation subgrade soils will likely be moisture sensitive, and surface water should be directed away from any excavation to avoid undercutting.

Given the appropriate site and soil conditions, we see no unusual constructability conditions that would inhibit the use of shallow foundations for this project.

7. EXISTING INTERSTATE PAVED SHOULDERS

Seventy (70) pavement cores and subsequent shallow soil test borings were performed along the existing interstate paved shoulders. Charts are provided in Section 5 of Appendix A that graphically summarizes the existing paved shoulder thickness and AASHTO soil classification of the subgrade material. From observations of the extracted cores, the existing I-26 shoulder asphalt thickness generally varies from six (6) inches to twenty (20) inches, the I-20 shoulder asphalt thickness generally varies from twelve (12) inches to fifteen (15) inches, and the I-126 shoulder asphalt thickness generally varies from one (1) inch to ten (10) inches. The thin asphalt shoulder sections encountered along I-126 are confined to areas near the existing Colonial Life Blvd. interchange.

From the soil test borings and subsequent CBR testing, we note that the quality of the subgrade material below the existing paved shoulders varies from fair to poor. Several borings along I-26, I-20, and I-126 indicated subgrade material with an AASHTO classification higher than A-4. The following table summarizes the existing paved shoulder data along the interstates.

Existing Interstate Paved Shoulder Data								
Interstate ID	Pavement Thickness (in)				CBR @ 95% Compaction			
	No. Data Points	Max	Min	Avg	No. Data Points	Max	Min	Avg
I-26	59	22	4	11	11	18.3	1.8	8.0
I-20	20	31	8	14	7	12.8	2.5	7.7
I-126	8	11	1	7	3	8.5	5.9	7.4

8. LIMITATIONS OF REPORT

This report has been prepared in accordance with generally accepted geotechnical engineering practice for specific application to the referenced project. The conclusions and recommendations contained herein are based upon the provided test borings and testing result data, contained within, and applicable standards in this geographic area at the time this report was prepared. No other warranty, expressed or implied, is made.

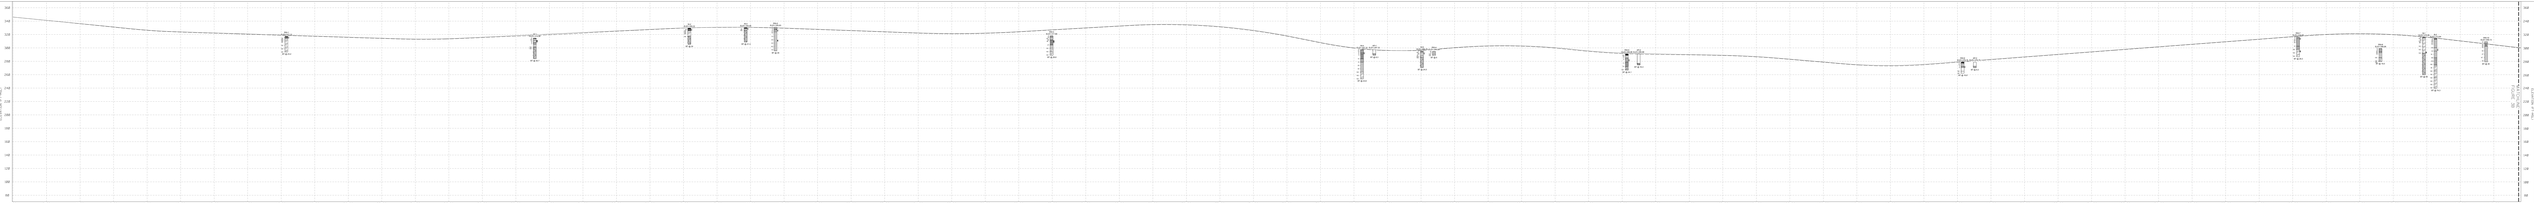
NOTES

1. THE NOMENCLATURE FOR EACH REFERENCED ALIGNMENT ON THE SUBSURFACE PROFILE DRAWINGS WAS DERIVED FROM THE HDR DRAWINGS RELATIVE TO THE RECOMMENDED PREFERRED ALTERNATIVE.

2. THE GENERALIZED SUBSURFACE PROFILES ARE PROVIDED ONLY FOR ILLUSTRATIVE PURPOSES. THE INTENT OF THESE DRAWINGS IS TO PROVIDE THE READER WITH VERY GENERAL INFORMATION ON SOILS, CUTS, AND FILLS. VARIATIONS IN THE INDICATED SUBSURFACE CONDITIONS WILL BECOME EVIDENT ONCE ADDITIONAL BORINGS ARE PERFORMED.



The generated subsurface profiles are provided only for illustrative purposes. The intent of these drawings is to present a general view of the subsurface information as was sure, and the conditions may vary. Under actual field conditions, we assume evident strict additional borings are performed.

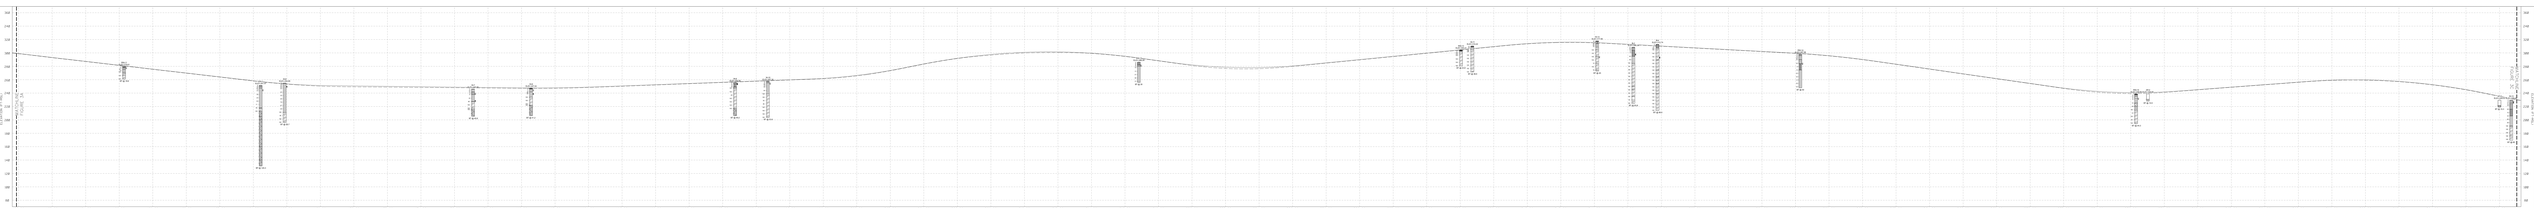
DRAWING TITLE: GEOLOGICAL PROFILE

DRAWING NO: DRAWING NO

SCALE: AS SHOWN

DATE: 08.11.2021



The generated subsurface profiles are intended only for illustrative purposes. The intent of these drawings is to communicate, in a general way, subsurface information at each site, and they should not be relied upon as representing conditions. All borehole evident strip additional borings are performed.

3	Harbison Blvd over I-26	2	B-1/B-2	25-30	Drilled?? (B-1) Driven (B-2)	30-70	50-70	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock. Potential issues with lateral stability; may require predrilling.	??	0-40	24-40	PWR/Soft Rock	B-1 shows PWR near the ground surface. B-2 shows PWR ~40 ft from the ground surface and did not encounter hard rock to the depths explored. Piles will likely require some predrilling to achieve the minimum embedment for lateral stability.	PWR/Soft Rock	0-40	24-40	Construction casing is anticipated to top of PWR. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR/soft rock and/or end bearing on PWR/soft rock.	0-10	20	PWR/Hard Residuum	Spread footings may be suitable at this site. For B-1 subsurface conditions, the spread footings would bear on PWR and should have sufficient bearing capacity realtive to settlement. For B-2 soil conditions, the spread footings would bear on hard residuum and settlement and bearing capacity would be more of an issue. Groundwater issues are considered low risk.
4	Piney Grove Rd over I-26 **(RETAIN)**	N/A		--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--
5	St. Andrews Rd over I-26	2	B-5/B-6/ B-6A/B-7/B-65	25-30	Driven	40-50	70-80	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	Drilled	20	40	PWR	PWR profile is relatively consistent without much elevation change.		20	45	Construction casing is anticipated to top of PWR. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR/soft rock and/or end bearing on PWR/soft rock.	15	5	PWR	Spread footings will be difficult to design/build due to shallow groundwater and depth to a stable bearing stratum.
6	St. Andrews Ramp B over I-26CD	1	B-5/RW-16	20	Driven	30	NE	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	Drilled	10	45	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	PWR	10	45	Construction casing is anticipated in the top 10 ft. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR and/or end bearing on PWR.	10	0-5	PWR	Spread footings will be difficult to design/build due to shallow groundwater and depth to a stable bearing stratum.
6A	St. Andrews Rd over I-26CD	1	B-5/B-6	20	Driven	30	70	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	Drilled	10	45	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	PWR	10	45	Construction casing is anticipated in the top 10 ft. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR and/or end bearing on PWR.	10	0-5	PWR	Spread footings will be difficult to design/build due to shallow groundwater and depth to a stable bearing stratum.
7	I-26 Ramp DB over St. Andrews Ramp D, I-26, & I-26 Ramp BD	4	B-9/DH-2	30	Driven	80 (DH-2) NE (B-9)	NE (DH-2) 90 (B-9)	PWR/Soft Rock	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	Driven	60 (DH-2) N/A (B-9)	N/A (DH-2) 60 (B-9)	PWR/Soft Rock	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	PWR/Soft Rock	60 (DH-2) N/A (B-9)	N/A (DH-2) 60 (B-9)	Construction casing is anticipated to top of PWR. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR/soft rock and/or end bearing on PWR/soft rock.	60	20-30	PWR	Spread footings will be difficult to design/build due to shallow groundwater and depth to a stable bearing stratum.
8	I-26 over I-20	1	B-10/B-11	30	Driven	80 (B-10) 70 (B-11)	NE	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	Driven	50	N/A	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	PWR	50	N/A	Construction casing is anticipated to top of PWR. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR/soft rock and/or end bearing on PWR/soft rock.	20-30	15	Hard Residuum	Spread footings will be difficult to design/build due to groundwater at or near the stable bearing stratum elevation. On residuum, spread footing concept may yield bearing capacity and settlement issues.
9	Beatty Rd & Tram Rd over I-26	4	B-3/B-4	30	Driven	50 (B-3) 4 (B-4)	NE	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock. On the B-4 side, predrilling may be required to achieve the required lateral stability.	Drilled	25 (B-3) 4 (B-4)	N/A	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock. For B-3 subsurface conditions, piles may be driven, but will likely require hard driving conditions to advance the piles to the minimum tip EL for lateral stability.	PWR	25 (B-3) 4 (B-4)	N/A	Construction casing is anticipated to top of PWR. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR/soft rock and/or end bearing on PWR/soft rock.	5-10	10-20	Residuum/PWR	Spread footings may be suitable at this site. In the absence of using temp. shoring, the spread footings would bear on hard residuum or PWR. At this depth, settlement and bearing capacity would likely govern the spread footing design.
10	I-20 Ramp AC over I-20	3	B-17	40	Driven	100	130	Residuum	Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum.	Driven	55	85	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	PWR & Rock	55	85	Construction casing is anticipated in the top 10 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR/soft rock and/or end bearing on PWR/soft rock.	30	30	Hard Residuum	Spread footings will be difficult to design/build due to groundwater at or near the stable bearing stratum elevation. On residuum, spread footing concept may yield bearing capacity and settlement issues.
11	I-26 Ramp BD over I-20	2	B-17/B-18	30	Driven	85 (B-17) 70 (B-18)	155 (B-17) 100 (B-18)	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	Driven	50	80	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	PWR & Rock	50	80	Construction casing is anticipated in the top 10 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR/soft rock and/or end bearing on PWR/soft rock.	30	30	Hard Residuum	Spread footings will be difficult to design/build due to groundwater at or near the stable bearing stratum elevation. On residuum, spread footing concept may yield bearing capacity and settlement issues.
12	I-26 Ramp DB over I-20	2	B-24	25	Driven	40	NE	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	Drilled	15	N/A	PWR	Assuming a 10 ft depth to allow for proper footing thickness and footing embedment below final grades, about of 5 ft of soil is present above PWR. Predrilling operations are likely to achieve lateral stability.	PWR	15	N/A	Construction casing is anticipated to top of PWR. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR/soft rock and/or end bearing on PWR/soft rock.	15	20	PWR	Spread footings will be difficult to design/build due to depth to a stable bearing stratum. Bearing capacity may be achieved at a higher depth in the hard residuum, but brings on more risk.
13	I-20 Ramp CA over I-20	2	B-25	30	Driven	60	NE	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	Driven	30	N/A	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock. Some hard driving may be required to advance the piles to the minimum tip EL for lateral stability.	PWR	30	N/A	Construction casing is anticipated to top of PWR. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR/soft rock and/or end bearing on PWR/soft rock.	15	20	PWR	Spread footings will be difficult to design/build due to depth to a stable bearing stratum. Bearing capacity may be achieved at a higher depth in the hard residuum, but brings on more risk.
14	I-26 Ramp BD over I-26	2	B-14/B-14A	30	Driven	100	NE	Residuum/PWR	Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Driven	70	N/A	PWR	Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Residuum & PWR	70	N/A	Construction casing is anticipated in the top 10-20 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/PWR and/or end bearing on PWR.	40-50	15	Hard Residuum	Spread footings are not likely to be used at this site due to soft soils near the ground surface. Significant cuts and temp. shoring below the groundwater table would be required to find a stable bearing elevation.
15	I-20 Ramp C1 over I-20 Ramp AC, I-26 Ramp BD, I-126 CD E & I-26	10	B-19/B-20/ 12/B-13	50 (B-19) 30 (B-13)	Driven	70 (B-19) 85 (B-13)	NE	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	Driven & Drilled	10-60	N/A	PWR	Shallow groundwater may inhibit the ability to excavate for the pile footing. Top of PWR varies along the profile. At some locations, the top of PWR is shallow relative to the existing grade and may require predrilling to achieve lateral stability requirements.	PWR	10-60	N/A	Construction casing is anticipated in the top 10-15 ft in residuum or on top of PWR. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/PWR and/or end bearing on PWR.	10-15	10-15	PWR/Hard Residuum	Spread footings will be difficult to design/build due to groundwater at or near the stable bearing stratum elevation. On residuum, spread footing concept may yield bearing capacity and settlement issues.
16	I-20 Ramp CA over I-26 Ramp DB	1	B-26/B-27	35	Driven	95 (B-26) 80 (B-27)	NE	Residuum/PWR	Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Driven	40-50	N/A	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	PWR	40-50	N/A	Construction casing is anticipated in the top 20-30 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/PWR and/or end bearing on PWR.	20-50	20-30	Hard Residuum	Spread footings may be suitable above the stable bearing stratum elevation.
17	I-26 Ramp DB over I-20 Ramp AC	1	B-21/B-22	20	Driven	80 (B-21) 90 (B-22)	NE	Residuum/PWR	Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Driven	80-90	N/A	Residuum/PWR	Bridge is located in a proposed cut section. Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Residuum & PWR	80-90	N/A	Construction casing is anticipated in the top 10-20 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/PWR and/or end bearing on PWR.	10-15	20-30	Hard Residuum	Spread footings will be difficult to design/build due to groundwater at or near the stable bearing stratum elevation. On residuum, spread footing concept may yield bearing capacity and settlement issues.
18	I-20 Ramp BD over I-26 Ramp DB	1	B-26/B-27	35	Driven	95 (B-26) 80 (B-27)	NE	Residuum/PWR	Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Driven	40-50	N/A	PWR	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock.	PWR	40-50	N/A	Construction casing is anticipated in the top 20-30 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/PWR and/or end bearing on PWR.	20-50	20-30	Hard Residuum	Spread footings may be suitable above the stable bearing stratum elevation.
19	I-20 Ramp CA over I-20 Ramp AC	1	B-22	20	Driven	70	NE	Residuum/PWR	Bridge is located in a proposed cut section. Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Driven	55-65	N/A	Residuum/PWR	Bridge is located in a proposed cut section. Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Residuum & PWR	55-65	N/A	Construction casing is anticipated in the top 10-20 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/PWR and/or end bearing on PWR.	10-15	15-25	Hard Residuum	Spread footings may be suitable at this site. In the absence of using temp. shoring, the spread footings would bear on hard residuum or PWR. At this depth, settlement and bearing capacity would likely govern the spread footing design.
20	I-26 Ramp BD over I-126 CD E	1	B-14/B-14A	30	Driven	100	NE	Residuum/PWR	Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Driven	70	N/A	PWR	Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Residuum & PWR	70	N/A	Construction casing is anticipated in the top 10-20 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/PWR and/or end bearing on PWR.	40-50	15	Hard Residuum	Spread footings are not likely to be used at this site due to soft soils near the ground surface. Significant cuts and temp. shoring below the groundwater table would be required to find a stable bearing elevation.
21	I-20 Ramp C2 over I-126 CD E	1	B-15	0	Driven	55	NE	Residuum/PWR	Bridge is located in a proposed cut section. Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Drilled/Driven	25	N/A	PWR	Bridge is located in a proposed cut section. The excavation will leave the finished grade ~25 ft above PWR. Piles may require predrilling for lateral stability.	PWR	25	N/A	Construction casing is anticipated to top of PWR. Below the casing tips, the shafts will develop the required resistance through either skin friction in PWR/soft rock and/or end bearing on PWR/soft rock.	20-30	10-20	Hard Residuum	Spread footings will be difficult to design/build due to groundwater at or near the stable bearing stratum elevation. On residuum, spread footing concept may yield bearing capacity and settlement issues.
22	I-20 Ramp AC over St. Andrews Ramp D, I-26 & I-26 Ramp BD	4	RW-21/B-9/ RW-24/ DH-2/RW-25	40 (RW-21) 12 (R-25)	Driven	100 (B-9) 60 (RW-25)	NE	Residuum/PWR	Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Driven	35-60	N/A	PWR	Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	PWR	35-60	N/A	Construction casing is anticipated in the top 10-20 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/PWR and/or end bearing on PWR/soft rock.	50-60	20-30	Hard Residuum	Spread footings will be difficult to design/build due to depth of the bearing layer. Large excavations would be required to reach this depth.
23	I-26 CD W1 over St. Andrews Ramp D	1	B-8	0	Driven	80	90	Residuum/PWR	St. Andrews Ramp D alignment will be cut significantly to create the vertical clearance for the bridge. Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Driven	40	50	PWR	Bridge is located in a proposed cut section. The excavation will leave the finished grade ~40 ft above PWR.	Residuum, PWR, & Rock	40	50	Construction casing is anticipated in the top 10 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/PWR/rock and/or end bearing on PWR/soft rock.	5-10	25	Hard Residuum	Spread footings may be suitable at this site. In the absence of using temp. shoring, the spread footings would bear on hard residuum. At this depth, settlement and bearing capacity would likely govern the spread footing design. The Contractor would have to drain/manage the perceived perched water at the site.
24	I-20 CD W2 over Bush River Ramp E	1	B-16	35	Driven	120	NE	Residuum	Some soft/firm silts under the water table that may experience strength loss under the design seismic event. Piles will develop the required driving resistance through a combintaion of skin friction and end bearing in/on residuum.	Driven	90	N/A	Residuum/PWR	Piles will develop the required driving resistance through a combintaion of skin friction and end bearing on hard residuum and/or PWR.	Residuum & PWR	90	N/A	Construction casing is anticipated to ~40 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/PWR and/or end bearing on PWR/soft rock.	40	35	Hard Residuum	Spread footings will be difficult to design/build due to depth of the bearing layer. Large excavations would be required to reach this depth. Soft/firm fine-grained soils underly a hard surficial crust. These soils would likely create settlement/bearing capacity issues.
25	Burning Tree Rd Over I-20	4	B-23/B-28	10	Driven (B-23) Drilled?? (B-28)	90 (B-23) 20 (B-28)	NE	Residuum/PWR	If subsurface conditions are as indicated by B-23, then piles can likely be driven with a properly sized hammer. The subsurface conditions from B-28 may require predrilling to achieve lateral stability requirements. Under B-28 subsiface conditions, pile driving will likely deal with some drivability concerns. Piles will develop the required driving resistance through either or both skin friction and end bearing in residuum/PWR.	Driven & Drilled	5-75	N/A	Residuum/PWR	Given B-28 subsurface conditions, predrilling operations are likely to achieve lateral stability requirements. For B-28 subsurface conditions, pile driving will likely have to deal with drivability issues. Piles will develop the required driving resistance through either or both skin friction and end bearing in residuum/PWR.		5-75	N/A	Construction casing is anticipated in the top 10 ft in residuum and/or PWR. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/PWR and/or end bearing on PWR/soft rock.	5-10	20-40	Hard Residuum/PWR	Spread footings may be suitable at this site. In the absence of using temp. shoring, the spread footings would bear on hard residuum. At this depth, settlement and bearing capacity would likely govern the spread footing design. Settlement and bearing capacity would likely govern the design.
26	Bush River Rd over I-26 & I-126	4	B-29/B-30	30	Driven/Drilled	70-80	70 to >100	PWR or Rock	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock. Lenses of PWR encountered from approximately 42 to 85 feet below planned finished grade. Pre-drilling may be required to achieve planned pile tip elevation. Note that rock was not encountered in boring B-30 on the east side of the bridge within about 100 feet below planned finished grade.	Driven/Drilled	40-55	40-70+	PWR or Rock	Lenses of PWR encountered from approximately 13 to 55 feet below grade. Pre-drilling may be required to achieve planned pile tip elevation. Note that rock was not encountered in boring B-30 on the east side of the bridge within about 100 feet below planned finished grade. A core barrel may be required to excavate the rock socket.	PWR/Rock	40-55	40-75+	Construction casing is anticipated in the top 30-60 ft in residuum and PWR. Lenses of PWR encountered from approximately 13 to 55 feet below grade. Rock auger or core barrel may be required to penetrate PWR lenses or isolated boulders to achieve shaft bearing elevation. Preliminary boring data suggests shafts may bear in either sound rock or PWR. Longer rock sockets may be required for shafts bearing in PWR. A core barrel may be required to excavate the rock socket.	N/A	7 to 20	Existing Fill or Residuum.	Shallow Foundation not recommendend. Settlement and Bearing Capacity Issues likely due to anticipated loading.
27	I-26 over I-126 CD E	1		20-May	Driven/Drilled	NE-37	30 to 75	PWR or Rock	Piles will develop the required driving resistance primarily through end bearing on PWR or soft rock. Pre-drilling may be required to penetrate lenses of PWR or isolated rock boulders above planned tip elevations. Pre-drilling into rock may also be required to achieve lateral fixity due to shallow rock.	Driven/Drilled	NE-20	25-55	PWR or Rock	Pre-drilling may be required to penetrate lenses of PWR or isolated rock boulders above planned tip elevations. Pre-drilling into rock may also be required to achieve lateral fixity due to shallow rock.	Rock	NE-20	25-55	Construction casing is anticipated in the top 20 ft in residuum. Rock Auger or core barrel may be required to penetrate PWR lenses or isolated boulders. Longer rock socket may be required due to low quality weathered and foliated schist bedrock. A core barrel may be required to excavate the rock socket.	N/A	20 to 23	Alluvium or Residuum	Shallow Foundation not recommendend. Settlement and Bearing Capacity Issues likely due to anticipated loading.
28	I-26 Ramp CA over I-26 Ramp BD2	1	DH-3	20-Oct	Driven	80	80	Bedrock	Potential for boulders at this site. If boulders are encountered at shallow depths, the predrilling operations may need to be employed. Piles will develop the required driving resistance through either or both skin friction and end bearing on bedrock.	Driven	60	60	Bedrock	Potential for boulders at this site. If boulders are encountered at shallow depths, the predrilling operations may need to be employed. Piles will develop the required driving resistance through either or both skin friction and end bearing on bedrock.	Residuum/Rock	60	60	Potential for boulders at this site. Construction casing is anticipated in the top 20 ft in residuum. Below the casing tips, the shafts will develop the required resistance through either skin friction in residuum/rock and/or end bearing on rock. A core barrel may be required to excavate the rock socket.	20+	5-10	Residuum	Spread footings will be difficult to design/build due to groundwater above the stable bearing stratum elevation.
29	I-26 Ramp CA over I-126 CD E	1	B-36/B-36A	10	Driven/Drilled	60-70	80	PWR or Rock	Pre-drilling may be required to penetrate lenses of PWR or isolated rock boulders above planned tip elevations. Possible rock boulder encountered in boring B-36A at approx. 49 feet below planned finished grade.	Driven/Drilled	50-60	70	PWR or Rock	Estimated pile length accounts for proposed estimated cut depths for underpass. Pre-drilling may be required to penetrate lenses of PWR or isolated rock boulders above planned tip elevations. Pre-drilling into rock may also be required to achieve lateral fixity due to shallow rock.	Rock	50-60	70	Construction casing is anticipated in the top 20-30 ft in residuum. Estimated shaft length accounts for estimated cut depths for underpass. Rock Auger or core barrel may be required to penetrate PWR lenses or isolated boulders. Longer rock socket may be required due to low quality weathered and foliated schist bedrock. A core barrel may be required to excavate the rock socket.	N/A	15	Alluvium or Residuum	Shallow Foundation not recommendend. Settlement and Bearing Capacity Issues likely due to anticipated loading.

North Charleston, South Carolina 29405

Re: Geotechnical Subsurface Data Report: Revision 1
Carolina Crossroads
Richland/Lexington County, South Carolina
SCDOT Project ID P027662
F&ME File No. G5662.01

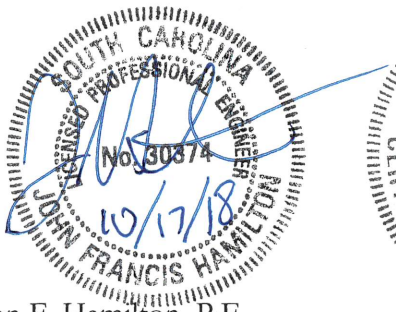
Mr. Kinard:

Submitted herein is the geotechnical subsurface data report for the above referenced project. Included is a summary of F&ME's subsurface data and the laboratory test results.

It has been a pleasure working with you on this project, and we appreciate the opportunity to be of service. Please notify us if there are any questions.

Sincerely,

F&ME CONSULTANTS



John F. Hamilton, P.E.
Geotechnical Design Manager

Bradley M. Fischer, E.I.T.
Geotechnical Staff Professional

Section 6	UD Preparation Logs
Section 7	Laboratory Test Results

1. PROJECT DESCRIPTION

The project is located just outside the City of Columbia, South Carolina. A site location plan is presented in the Section 1 of the Appendix.

It is our understanding that the project will consist of widening Interstate 26, Interstate 126, and Interstate 20 near the intersection of Interstate 26 and Interstate 20. In addition, select existing overpass bridges are designated for replacement to facilitate the interstate widenings, and new bridge construction is planned to accommodate the proposed turbine interchange. In total, the project extends approximately nine (9) miles along I-26, two (2) miles along I-20, and just over one (1) mile on I-126. Based on the RA1 alignment, a total of forty-six (46) bridges are planned for construction. Based on the conceptual drawings, the proposed bridge and roadway construction will mostly require fill placement, but there are locations where large cuts are required to meet the planned roadway grade. The cuts are mostly confined to the I-26/I-20 intersection. Furthermore, several retaining walls, sound walls, and overhead sign foundations are planned throughout the corridor. Each of these roadway structures contains a component that will require geotechnical design.

The geotechnical field investigation was performed by F&ME in general accordance with the 2010 SCDOT Geotechnical Design Manual (GDM) version 1.1 and the Scope of Services agreement. The information contained in this subsurface data report pertains to only the testing performed by F&ME. For the results from the testing performed by S&ME, refer to the S&ME Geotechnical Subsurface Data Report. S&ME's report is provided as Appendix C in the project's Geotechnical Base Line Report.

2. SUBSURFACE INVESTIGATION

From January 3 to July 2, 2018, thirty-one (31) bridge soil test borings (designated as B-1 through B-28, B-6A, B-14A, and B-63), twenty (20) wall soil test borings (designated as W-1 through W-17, W-20, W-21, and W-26), thirty-five (35) roadway embankment soil test borings (designated as RW-1 through RW-34, and RW-28A), four (4) soil test borings for downhole seismic testing (designated as DH-1 through DH-3, and DH-3A), twenty-one (21) auger borings (designated as AP-1 through AP-21), and twenty (20) bulk soil samples were performed along the conceptual RA1 corridor.

The soil test borings were advanced utilizing a CME 550 drill rig and a CME 45B drill rig. Rotary wash drilling techniques were used to maintain a stable borehole. Standard Penetration Tests (SPT) tests were continuously obtained in the top ten (10) feet of each test boring. Following the continuous sampling, SPT samples were obtained at regular, five (5) foot intervals throughout the remaining depths of the borings. SPT samples were performed in general accordance with ASTM D-1586 to determine the relative densities and consistencies of the subsurface soils and to collect subsurface soil samples. An automatic hammer was used to perform the SPTs. The measured energy ratio for the CME 550 hammer is 81%. The measured energy ratio for the CME 45B hammer is 84%. The bridge borings and wall borings were advanced to either a target depth or tri-cone roller bit drilling refusal, whichever was shallower. Where a drilling refusal condition was encountered, the borings were subsequently advanced into rock using NQ sized rock coring equipment. The roadway embankment borings were advanced to either a target depth or tri-cone roller bit drilling refusal, whichever was

shallower, and were subsequently terminated. The downhole seismic borings were advanced to a minimum depth of 120 feet to facilitate the geophysical testing in the upper 100 feet. Within the seismic borings and where a drilling refusal condition was encountered, the borings were subsequently advanced into rock using NQ sized rock coring equipment to the minimum depth.

The auger borings were performed for the primary purpose of collecting intact, Shelby Tube samples. SPT testing was not performed within the auger borings. The auger borings were advanced to target depths and subsequently terminated.

The bulk soil samples were performed to either provide soil strength parameters for the existing embankment soils or provide soil strength parameters in areas designated for excavation. The bulk soil samples were collected to a depth of five (5) feet below the existing ground surface and subsequently terminated.

The soil samples collected during the subsurface investigation were examined and logged in the field by F&ME personnel, sealed in plastic bags, and transported to F&ME's laboratory for further examination and analyses.

Rock cores collected from the subsurface investigation were also transported to the laboratory for visual inspection and for selecting specimens for laboratory testing. Photos of the recovered rock core specimens are provided in Section 5 of the Appendix.

We have provided Boring Location Plans in Section 2 of the Appendix. The boring location plans display the locations of the borings performed during F&ME's subsurface investigation(s). Individual boring logs are provided in Section 3 of the Appendix.

3. LABORATORY TESTING PROGRAM

Select soil and rock samples from the borings were tested in F&ME's AASHTO certified laboratory to determine physical and engineering properties. These tests were used to identify the strength and behavioral characteristics of the soils as well as to verify the field classifications by the AASHTO classification system and the Unified Soil Classification System (USCS). The laboratory testing program is summarized in the following table. These quantities represent tests performed only by F&ME.

Laboratory Testing Table	
Test Type	Quantity
Moisture Content	297
Grain Size w/ Wash #200	311
Atterberg Limits	313
CU Triaxial	33
UU Triaxial	1
Consolidation	4
Unconfined Compression - Rock	40
Standard Proctor	20
Electro-Chemical Series	28
Ignition Loss	4
Organic Content	5

All soil testing was conducted in general accordance with applicable ASTM/AASHTO standards. Data sheets presenting the results of F&ME's laboratory test program are provided in Section 7 of the Appendix.

4. LIMITATIONS OF REPORT

This report has been prepared in accordance with generally accepted geotechnical engineering practice for specific application to the referenced project. The soil descriptions, strata depths, and consistencies indicated on the provided documents are generalized and were interpreted by F&ME based on the subsurface conditions as encountered in the test borings. We have included the soil test boring logs in the Appendix for detailed descriptions of the encountered soil conditions. As with any geologic formation, the depth and thickness of the soil strata will vary across the site. Although the test borings designate strata changes at specific depths in the description of the soil stratigraphy on the soil test boring logs, transitions between soil strata are generally gradual. Therefore, the outlined subsurface profile shown on the soil test boring logs should only be considered general on-site soil conditions and should not be utilized as an absolute indicator.

SECTION 5 ROCK CORE PHOTOS

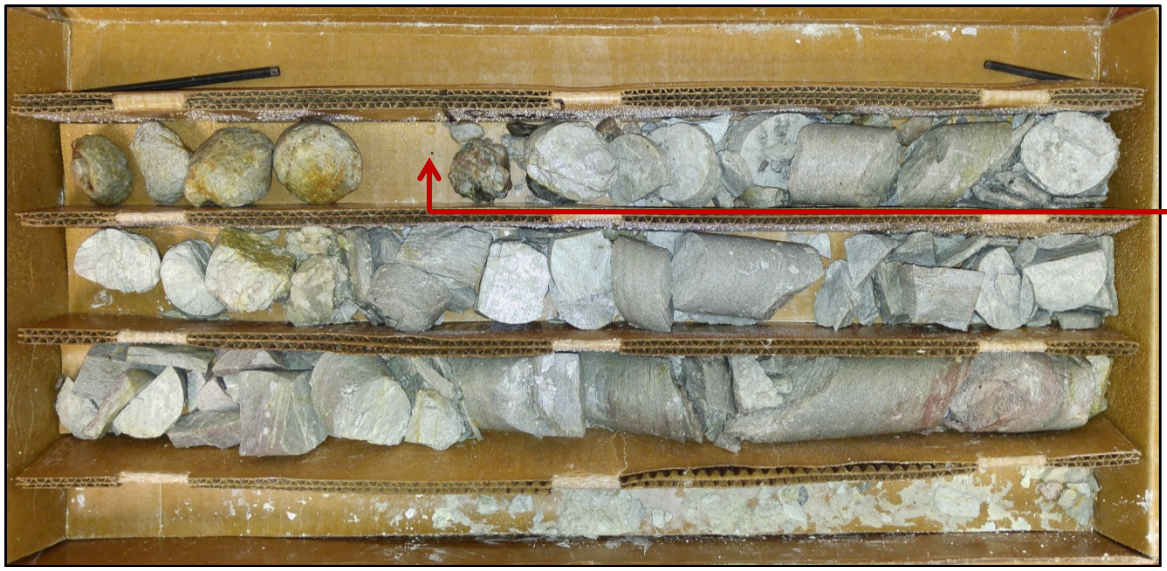
I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-1: S-757 Alignment – Station 40+96, Offset 27 ft - L

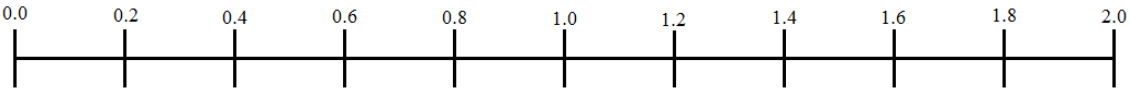
Begin Run 1
(23.8-26.0 ft)

Begin Run 2
(26.0-31.0 ft)

Begin Run 4
(36.0-41.0 ft)

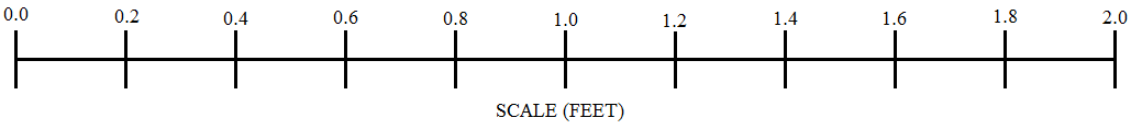


Begin Run 3
(31.0-36.0 ft)



Begin Run 5
(41.0-46.0 ft)

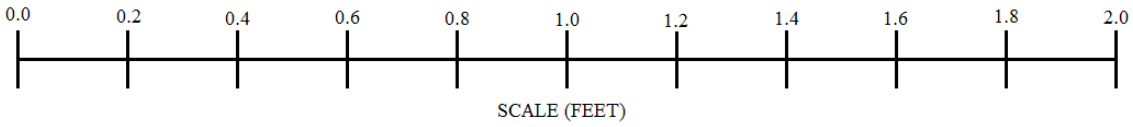
Begin Run 6
(46.0-51.0 ft)



I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-1: S-757 Alignment – Station 40+96, Offset 27 ft - L

Begin Run 7
(46.0-51.0 ft)



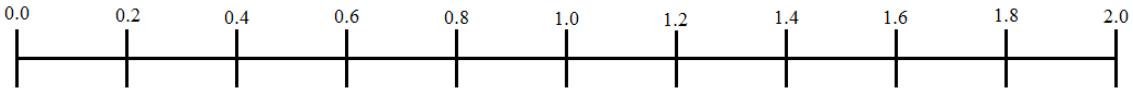
I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-6A: S-36 Alignment - Station 27+96, Offset 104 ft – R

Begin Run 1
(64.7-69.7 ft)

Begin Run 2
(69.7-74.7 ft)

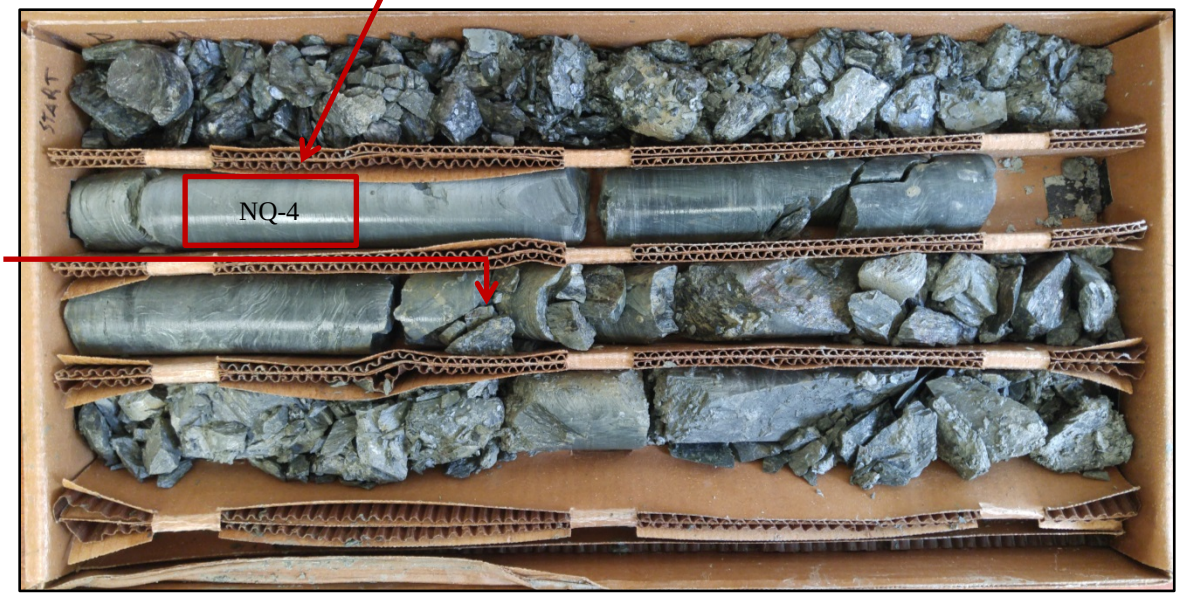
Begin Run 3
(74.7-79.7 ft)

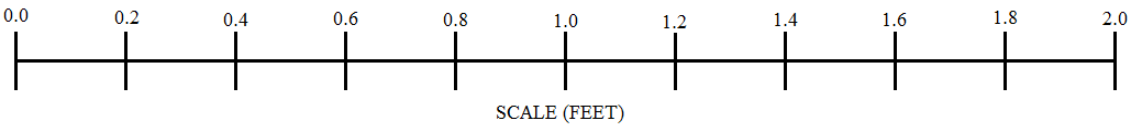


UC Strength
3,460 psi

Begin Run 4
(79.7-84.7 ft)

Begin Run 5
(84.7-89.7 ft)





F&ME CONSULTANTS

I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-7: S-36 Alignment - Station 31+21, Offset 161 ft – R

Begin Run 1
(43.6 – 45.9 ft)

Begin Run 2
(45.9 – 50.9 ft)

0.0 0.2 0.4 0.6 0.8 1.0 1.2 1.4 1.6 1.8 2.0

SCALE (FEET)

Begin Run 3
(50.9 – 55.9 ft)

UC Strength
740 psi

0.0 0.2 0.4 0.6 0.8 1.0 1.2 1.4 1.6 1.8 2.0

SCALE (FEET)

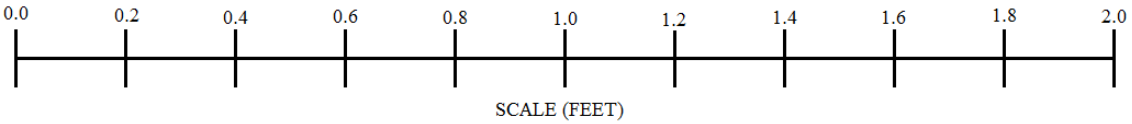
I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-7: S-36 Alignment - Station 31+21, Offset 161 ft – R

Begin Run 4
(55.9 – 60.9 ft)

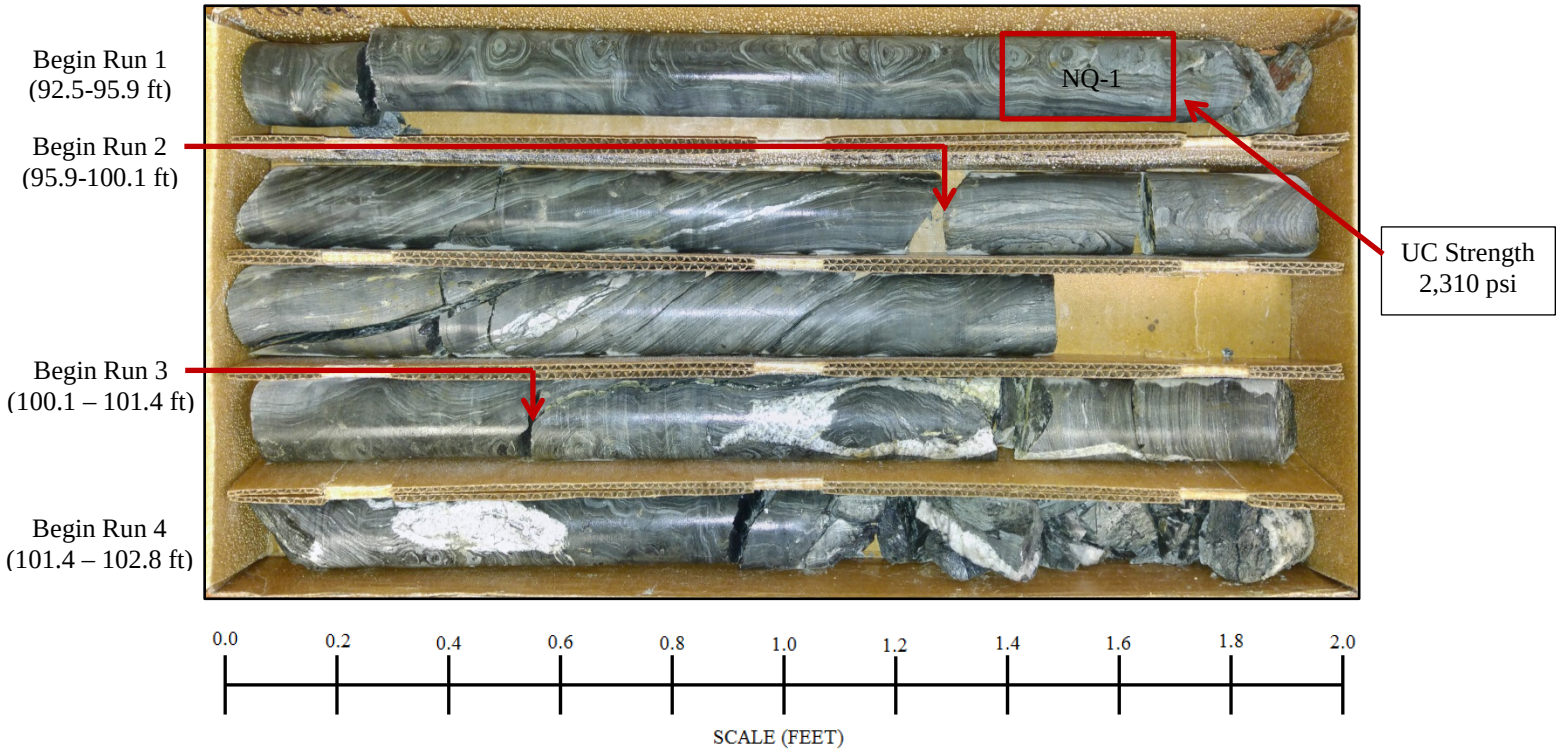
Begin Run 5
(60.9 – 63.6 ft)

UC Strength
1,360 psi



I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-8: 126CDW1 Alignment – Station 7332+07, Offset 17 ft – R



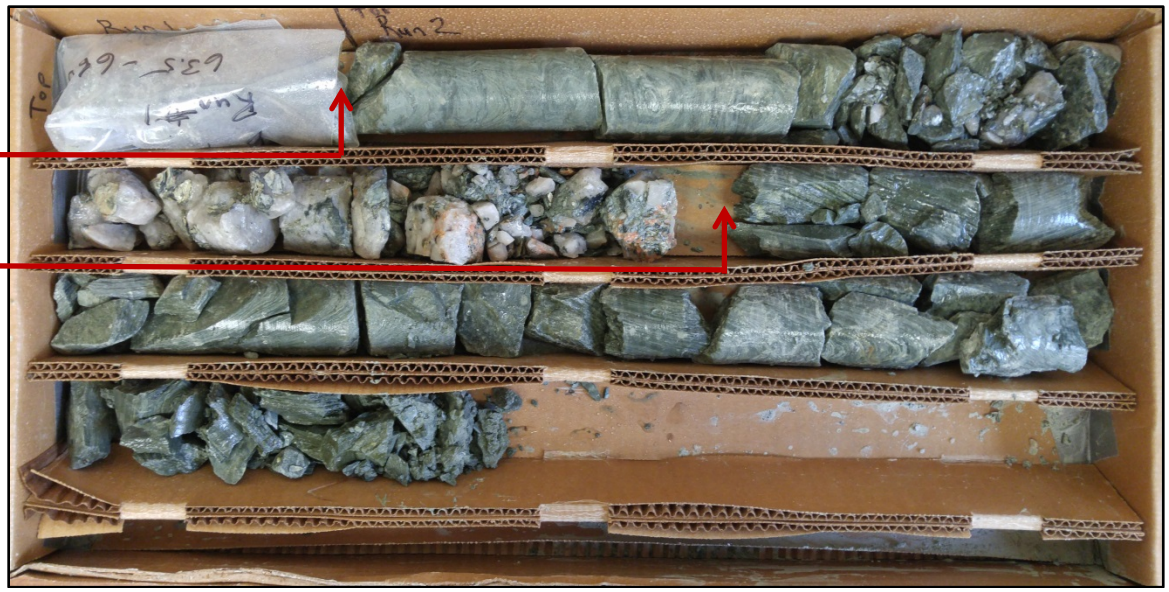
I-20/26/126 CORRIDOR IMPROVEMENTS

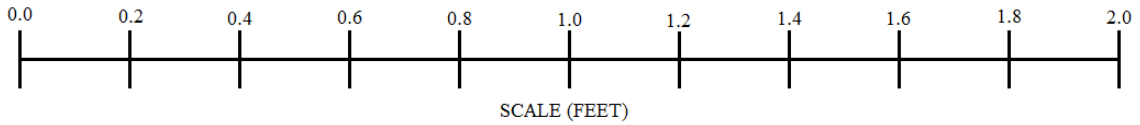
Boring B-9: I26RDB Alignment – Station 6389+63, Offset 155 ft – L

Begin Run 1
(63.6 – 66.0 ft)

Begin Run 2
(66.0 – 71.0 ft)

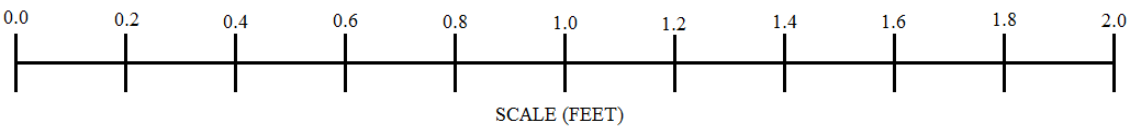
Begin Run 3
(71.0 – 76.0 ft)





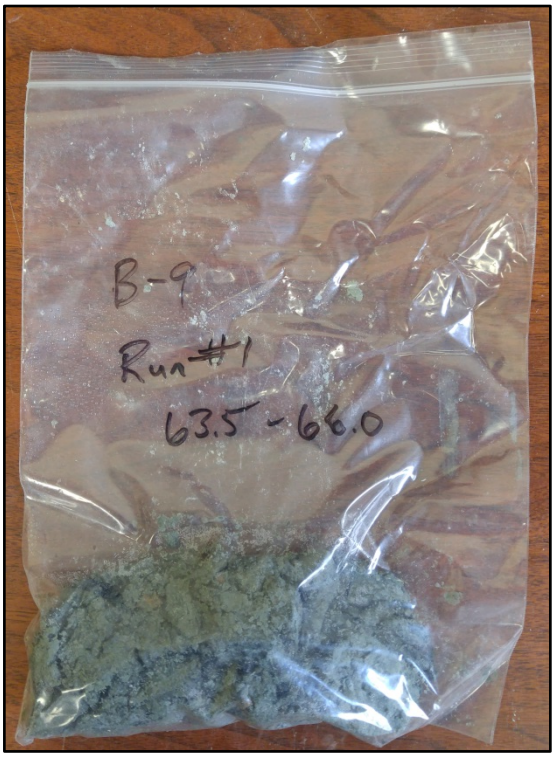
Begin Run 4
(76.0 – 81.0 ft)

Begin Run 5
(81.0 – 86.0 ft)



I-20/26/126 CORRIDOR IMPROVEMENTS

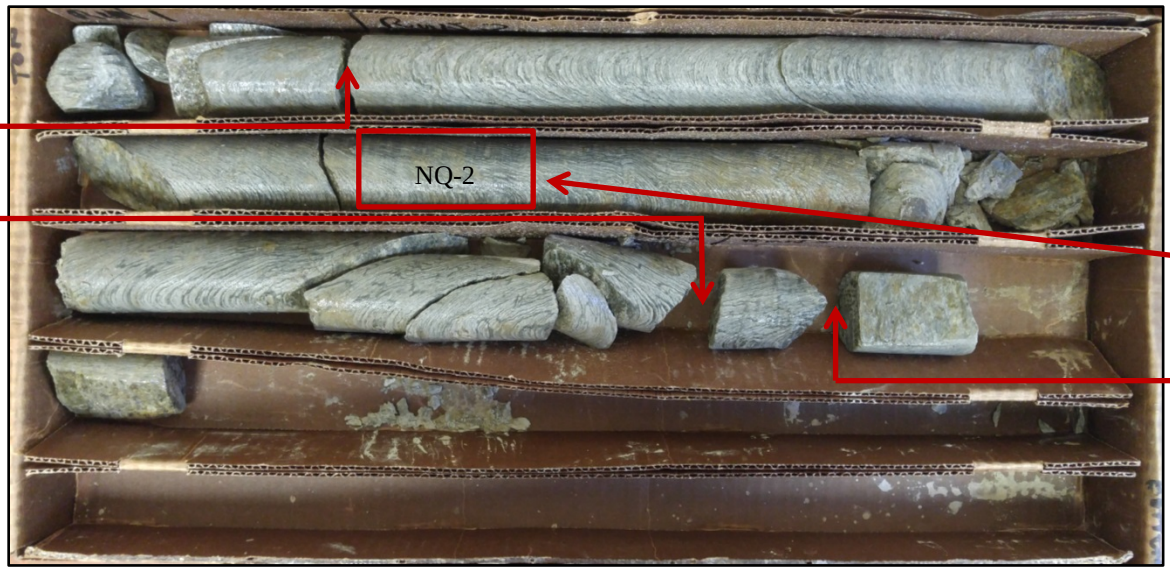
Boring B-9: I26RDB Alignment – Station 6389+63, Offset 155 ft – L

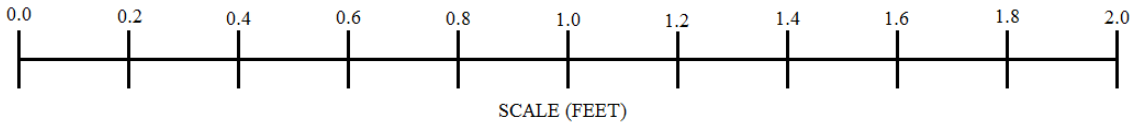


NQ-1

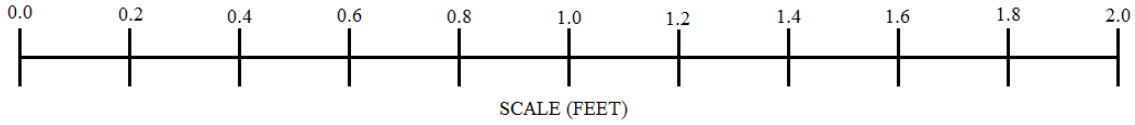
I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-11: I-26 Alignment – Station 341+66, Offset 78 ft – L



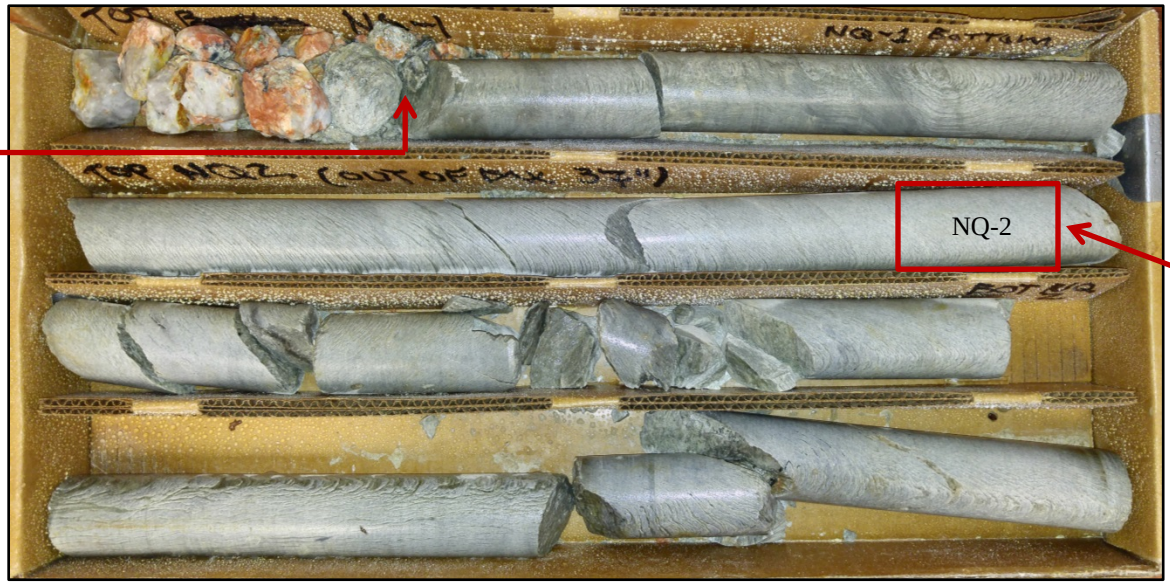


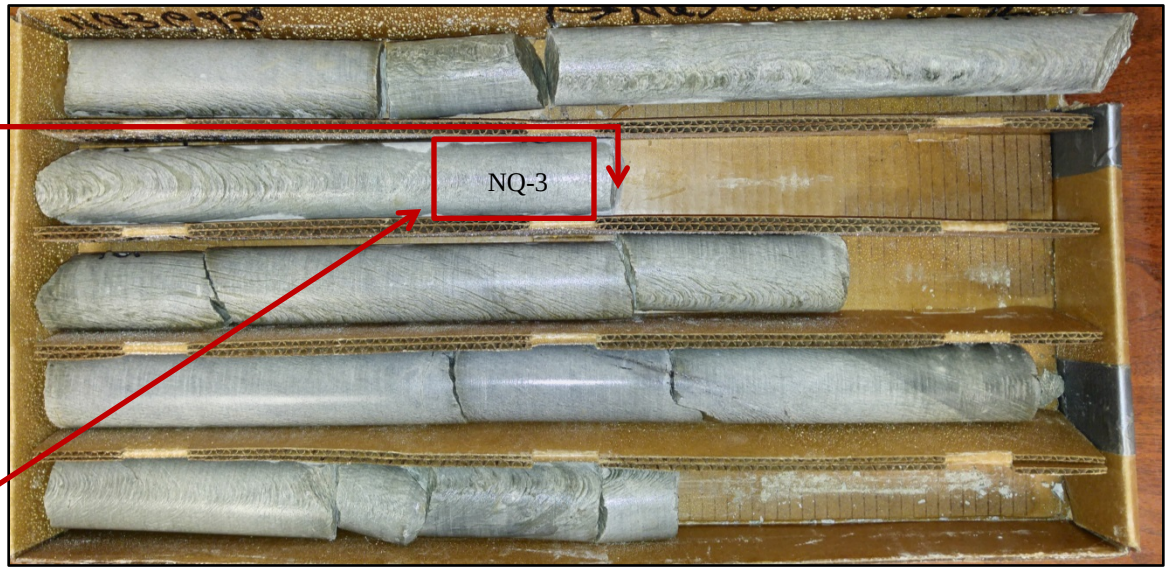
Approximately two (2) feet of rock was stuck and removed from the coring barrel during NQ-4 (89-4 – 94.4 ft)



I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-17: I20RAC Alignment – Station 3150+78, Offset 17 ft – L

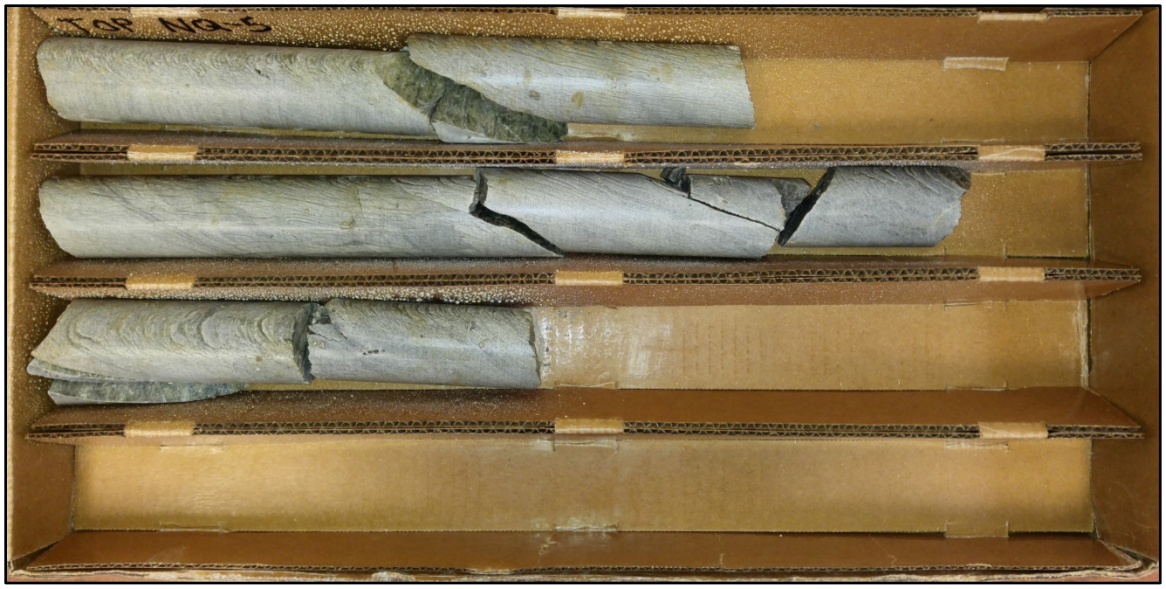


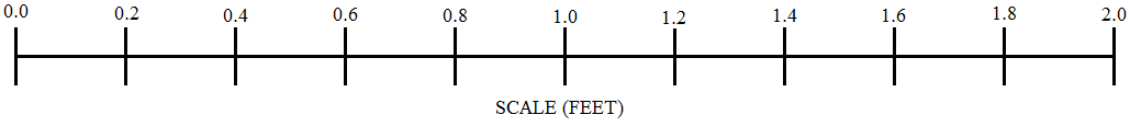


I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-17: I20RAC Alignment – Station 3150+78, Offset 17 ft – L

Begin Run 5
(101.0 – 104.5 ft)





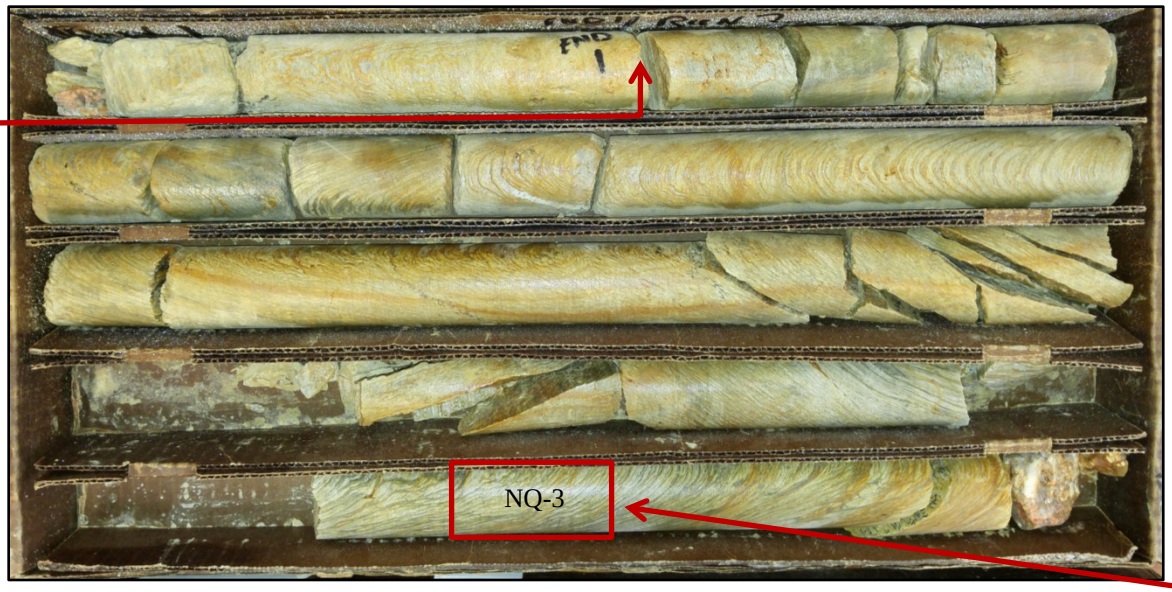
I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-18: I-20 Alignment – Station 154+03, Offset 100 ft – R

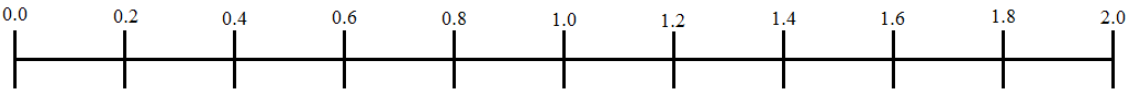
Begin Run 1
(73.6 – 75.1 ft)

Begin Run 2
(75.1 – 80.1 ft)

Begin Run 3
(80.1 – 85.1 ft)

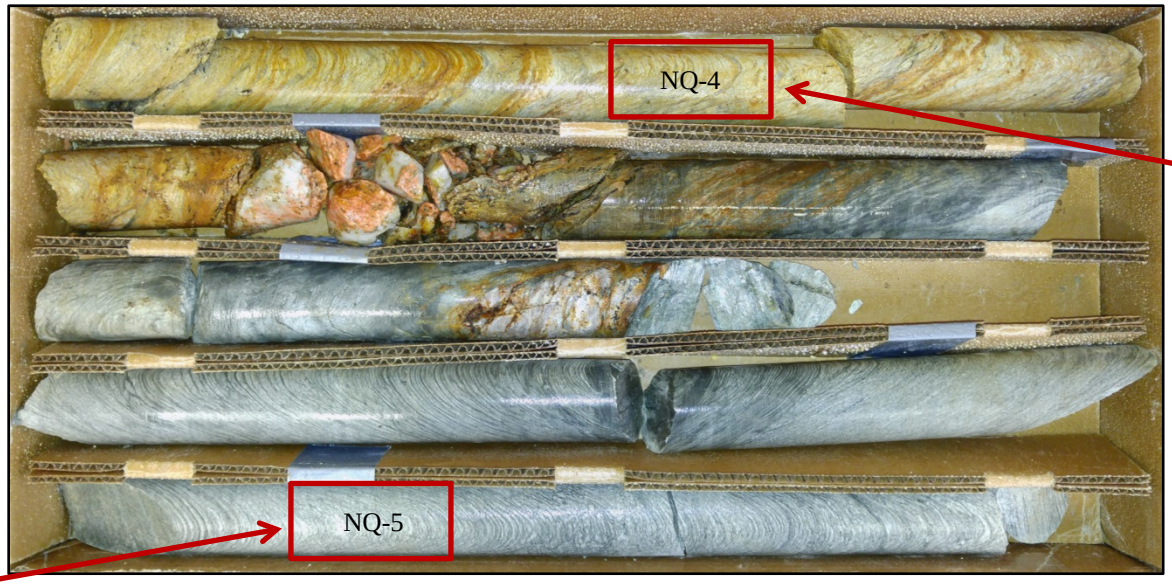


UC Strength
580 psi



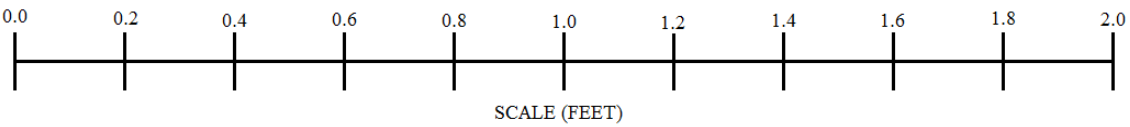
Begin Run 4
(85.1 – 90.1 ft)

Begin Run 5
(90.1 – 95.1 ft)



UC Strength
1,030 psi

UC Strength
1,590 psi

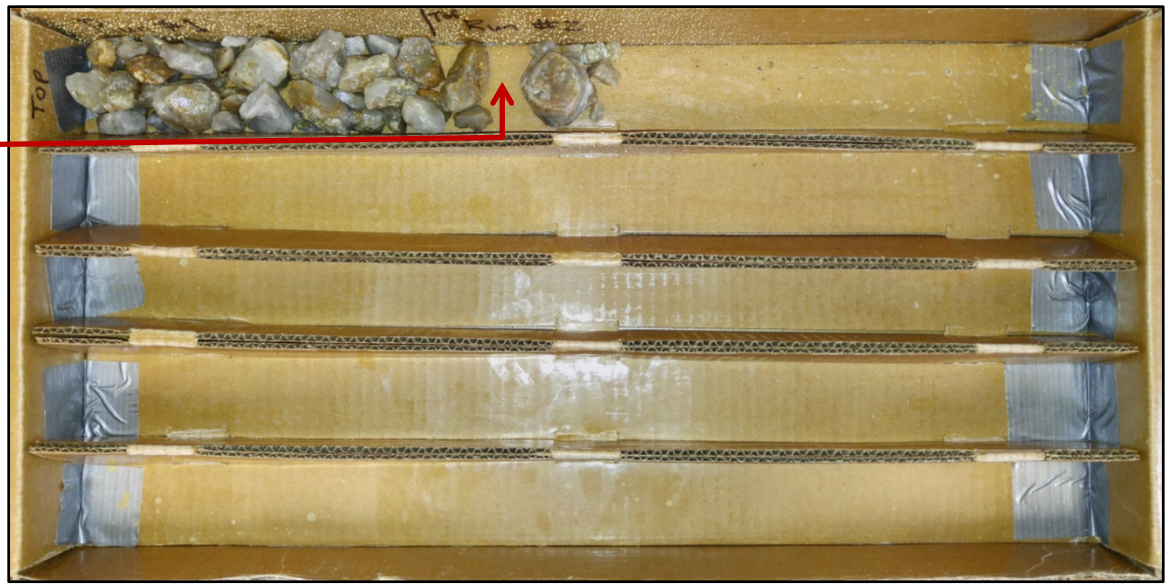


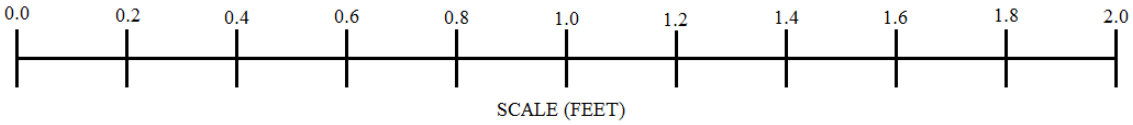
I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-19: I20RC1 Alignment – Station 5152+72, Offset 7 ft – R

Begin Run 1
(59.2 – 61.4 ft)

Begin Run 2
(61.4 – 66.4 ft)



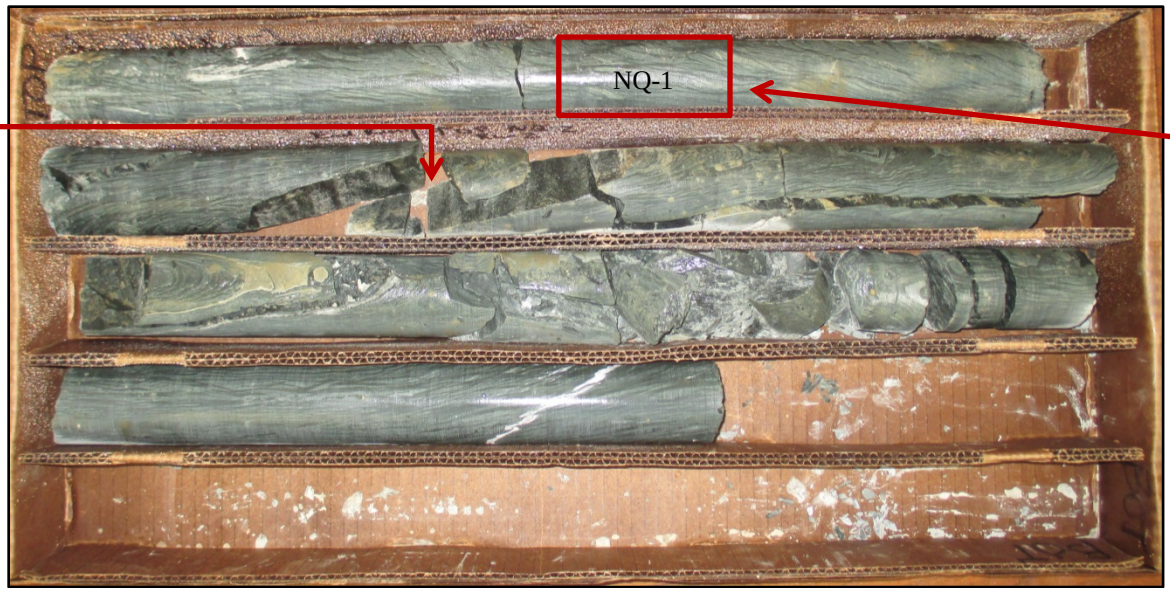


I-20/26/126 CORRIDOR IMPROVEMENTS

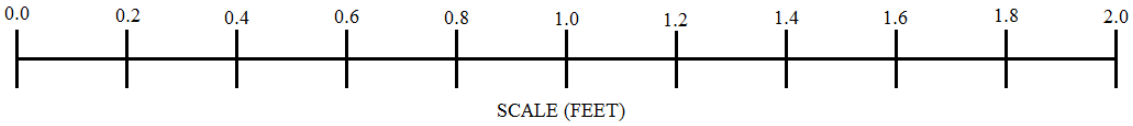
Boring B-63: S-36 Alignment – Station 30+38, Offset 99 ft – L

Begin Run 1
(43.0-45.4 ft)

Begin Run 2
(45.4-50.4 ft)

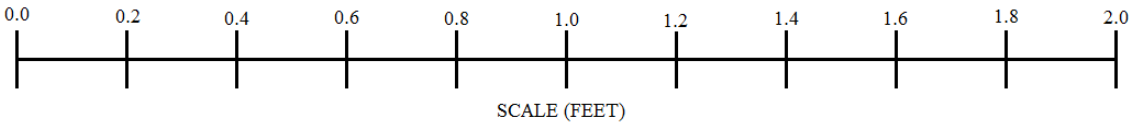


UC Strength
4,020 psi



Begin Run 3
(50.4-55.4 ft)

UC Strength
4,510 psi

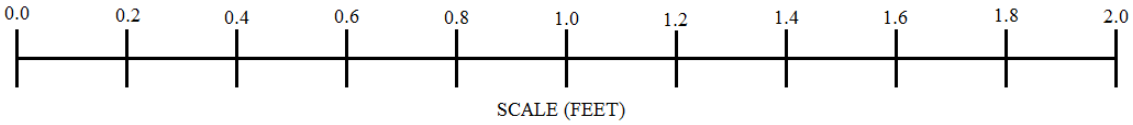


I-20/26/126 CORRIDOR IMPROVEMENTS

Boring B-63: S-36 Alignment – Station 30+38, Offset 99 ft – L

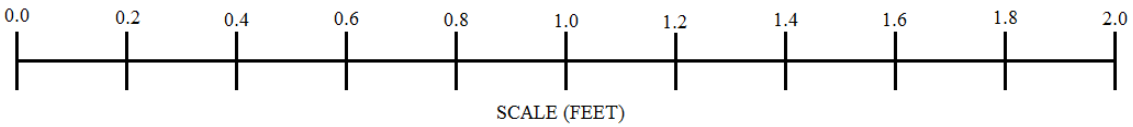
Begin Run 4
(55.4-60.4 ft)

UC Strength
7,270 psi



Begin Run 5
(60.4-65.4 ft)

UC Strength
4,110 psi

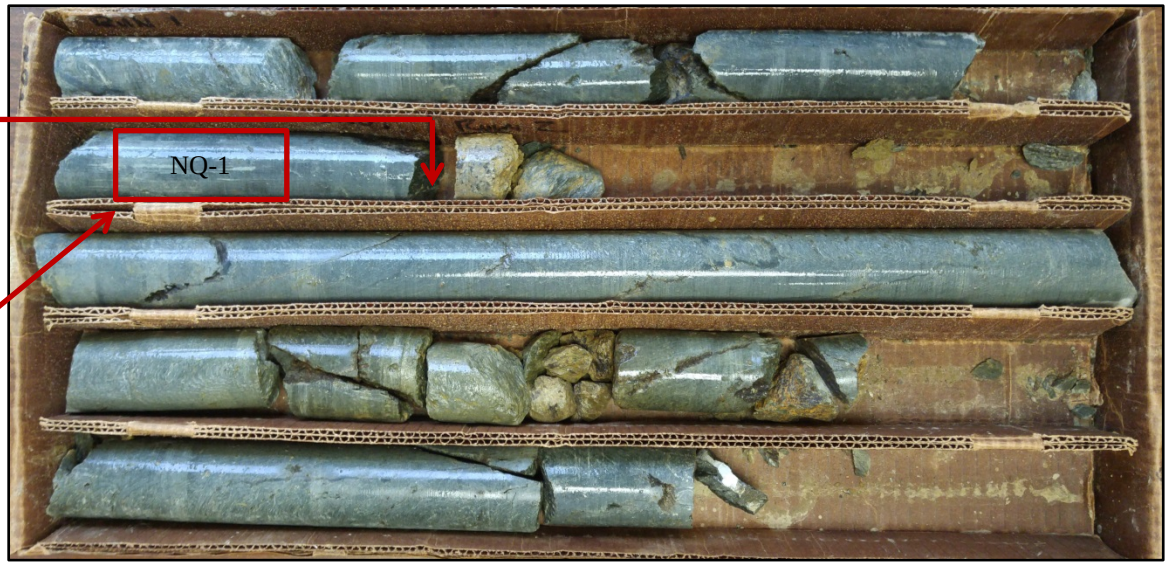


I-20/26/126 CORRIDOR IMPROVEMENTS

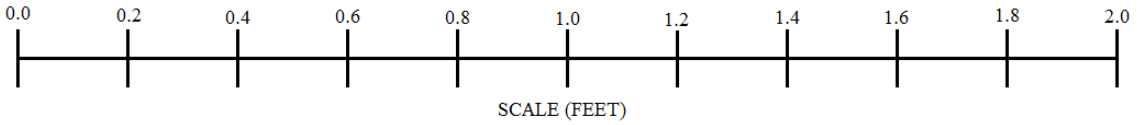
Boring DH-1: I-26 Alignment - Station 164+44, 85-ft LT

Begin Run 1
(38.6 – 41.3 ft)

Begin Run 2
(41.3 – 46.3 ft)



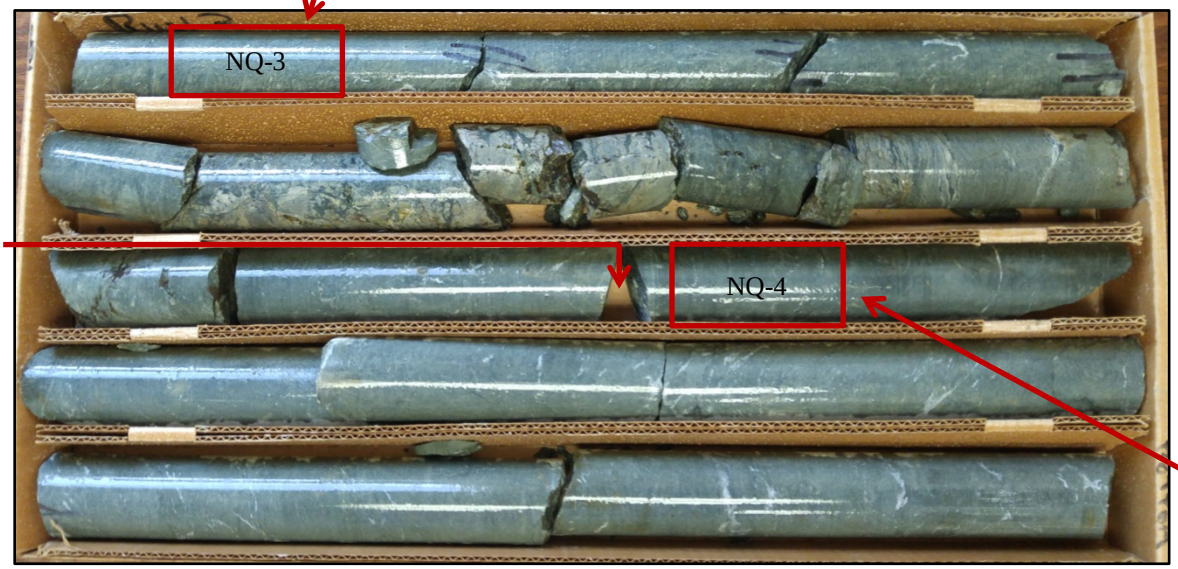
UC Strength
2,830 psi



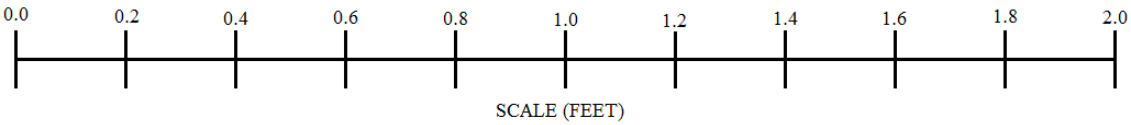
UC Strength
9,650 psi

Begin Run 3
(46.3-51.3 ft)

Begin Run 4
(51.3-56.3 ft)



UC Strength
9,020 psi



I-20/26/126 CORRIDOR IMPROVEMENTS

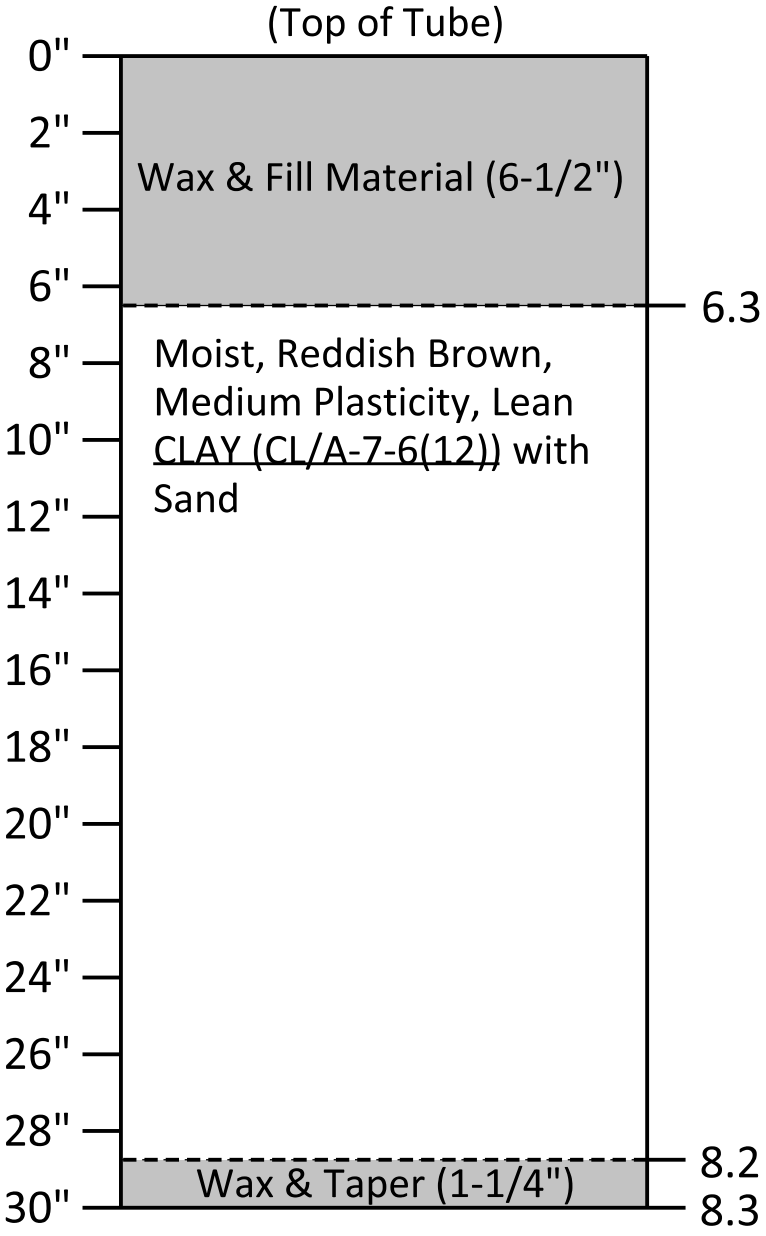
APPENDIX

SECTION 6 UD PREPARATION LOGS

UNDISTURBED SHELBY TUBE SAMPLE LOG

Shelby Tube UD-1



Prepared For: SCDOT

Project: Carolina Crossroads
I-20/26/126 Corridor Improvements

SCDOT Project ID: P027662

F&ME Project No.: G5662.01

Boring No.: AP-1

Sample Depth (feet): 6.0 - 8.3

Date Sampled: 5/23/2018

Date Pushed: 7/10/2018

Sample ID: 18-1029

Additional Comments:
The Shelby tube was advanced 28", and 23.5" of material was recovered. Sample was extruded by GeoTesting Express in Atlanta, GA. Grain size analysis, Atterberg limits and consolidated, undrained triaxial shear were performed on the sample.

LABORATORY TEST RESULTS

Prepared For: SCDOT

Project: Carolina Crossroads
I-20/26/126 Corridor Improvements

SCDOT Project ID: P027662

F&ME Project No.: G5662.01

Boring No.: AP-2

Sample Depth (feet): 14.0 - 16.3

Date Sampled: 5/23/2018

Date Pushed: 5/24/2018

Sample ID: 18-1034

Additional Comments:
Shelby tube was advanced 27", and 23-1/2" of material was recovered. The top 2" of sample were very soft and wet and were removed before extraction. Sample UD-1.A was also very soft and wet. Samples UD-1.B, UD-1.C, and UD-1.D were used for consolidated, undrained triaxial shear. Sample UD-2.E was used for grain size analysis and Atterberg limits.

LABORATORY TEST RESULTS							
Liquid Limit	Plastic Limit	Plasticity Index	%#200 Sieve	c (psi)	Φ	c' (psi)	Φ'

Boring No.: AP-3

Sample Depth (feet): 6.0 - 8.3

Date Sampled: 5/23/2018

Date Pushed: 6/19/2018

Sample ID: 18-1037

Additional Comments:
Shelby tube was advanced 28", and 27" of material was recovered. Approximately 2-1/2" of soil compression occurred during extraction. Samples UD-1.B, UD-1.C & UD-1.D were used for consolidated, undrained triaxial shear. Sample UD-1.C was used for grain size analysis and Atterberg limits.

LABORATORY TEST RESULTS							
Liquid Limit	Plastic Limit	Plasticity Index	%#200 Sieve	c (psi)	Φ	c' (psi)	Φ'

Sample Depth (feet): 8.0 - 10.5

Date Sampled: 5/23/2018

Date Pushed: 6/13/2018

Sample ID: 18-1035

Additional Comments:
Shelby tube was advance 30", and 22-1/2" of material was recovered. The top 3" of the tube containing recovered material was damaged and had to be removed. Sample UD-1.A contained a large piece of quartz gravel and a sizeable void. Sample UD-1.B contained a large void. Triaxial shear, grain size, and Atterberg limits were not performed .

Date Sampled: 5/23/2018

Date Pushed: 6/12/2018

Sample ID: 18-1030

Additional Comments:
The Shelby tube was advanced 28", and 23" of material was recovered. Spamples UD-1.A contained several voids. Samples UD-1.B & UD-1.C contained large pieces of quartz gravel throughout the specimens. Sample UD-1.C was used for grain size analysis and Atterberg limits. Sample UD-1.D was used for consolidation.

Boring No.: AP-6

Sample Depth (feet): 8.0 - 10.5

Date Sampled: 5/18/2018

Date Pushed: 6/14/2018

Sample ID: 18-0984

Additional Comments:
The Shelby tube was advanced 30", and 22" of material was recovered. Sample UD-1.A contained several voids filled with wax & a large chunk of wood. Approximately 1-1/2" of soil compression occurred during extraction. Very soft, wet silt squeezed out from between the tube and the piston head at the bottom of the tube during extraction.

Bottom of Tube

Moist, yellowish red clayey sand with gravel

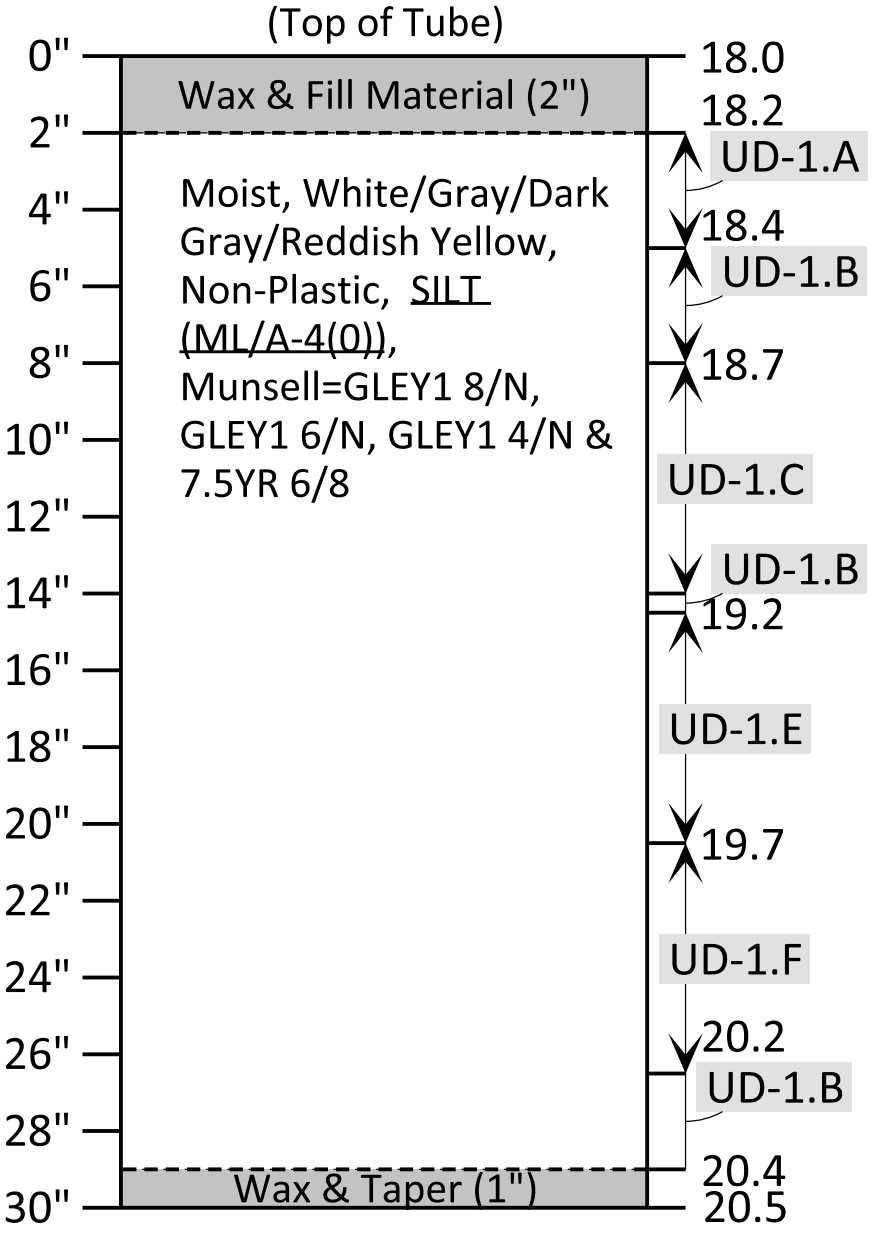
UNDISTURBED SHELBY TUBE SAMPLE LOG

Shelby Tube UD-1



Prepared For: SCDOT

Project: Carolina Crossroads I-20/26/126 Corridor Improvements

SCDOT Project ID: P027662

F&ME Project No.: G5662.01

Boring No.: AP-14

Sample Depth (feet): 18.0 - 20.5

Date Sampled: 5/22/2018

Date Pushed: 7/16/2018

Sample ID: 18-1009

Additional Comments:
Shelby tube was advanced 30", and 28" of material was recovered. Material was very dry and brittle and was possibly a layer of PWR. Sample UD-1.F was used for unconsolidated, undrained triaxial shear, grain size analysis, and Atterberg limits.

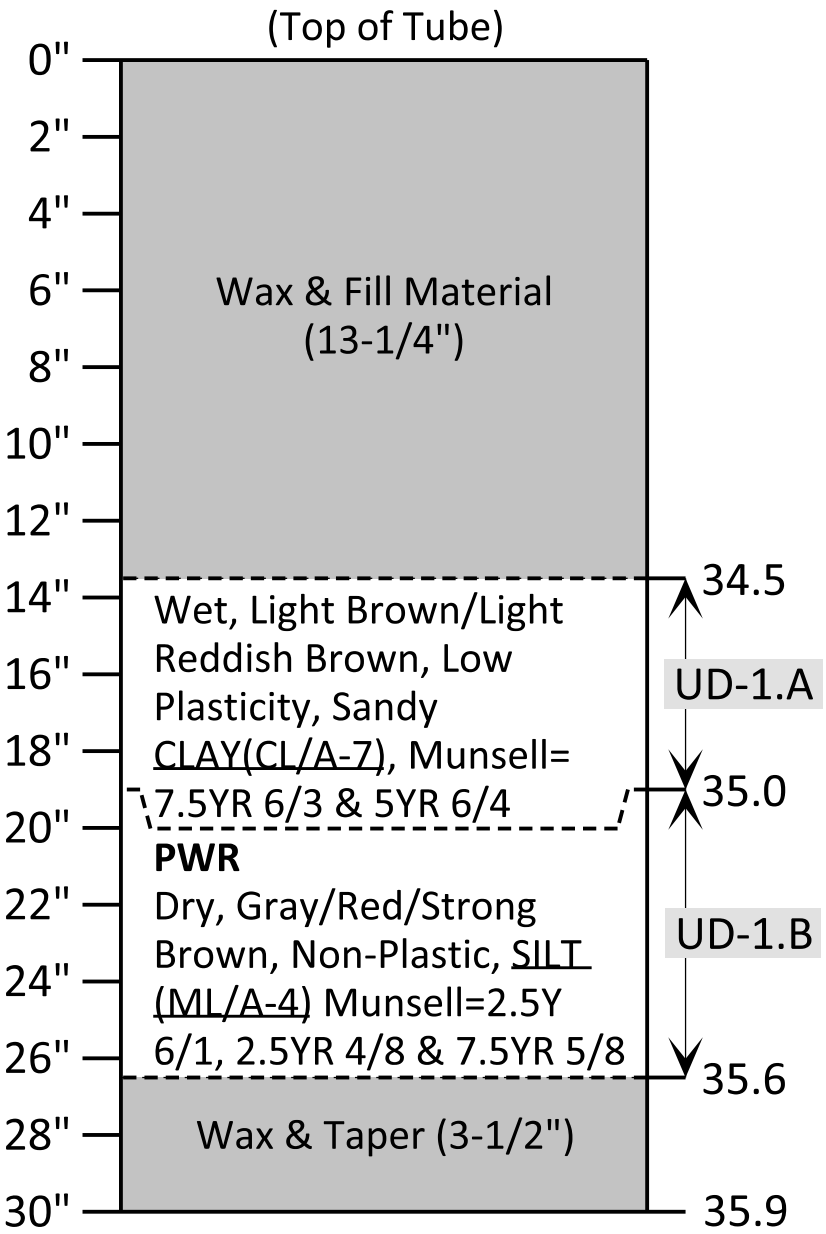
UNDISTURBED SHELBY TUBE SAMPLE LOG

Shelby Tube UD-1



Prepared For: SCDOT

Project: Carolina Crossroads
I-20/26/126 Corridor Improvements

SCDOT Project ID: P027662

F&ME Project No.: G5662.01

Boring No.: AP-16

Sample Depth (feet): 35.0 - 35.9

Date Sampled: 5/4/2017

Date Pushed: 5/10/2018

Sample ID: 18-0854

Additional Comments:
Shelby Tube was advanced 11" but recovered 17" of material. Soft material within the top 5-1/2" of the tube, in sample UD-1.A, appears to be cave-in material. Specimen UD-1.B was very dry and fell apart during extraction. Vertical banding and layering of the PWR was evident. Unconfined compression, grain size analysis, and Atterberg limits were not performed.

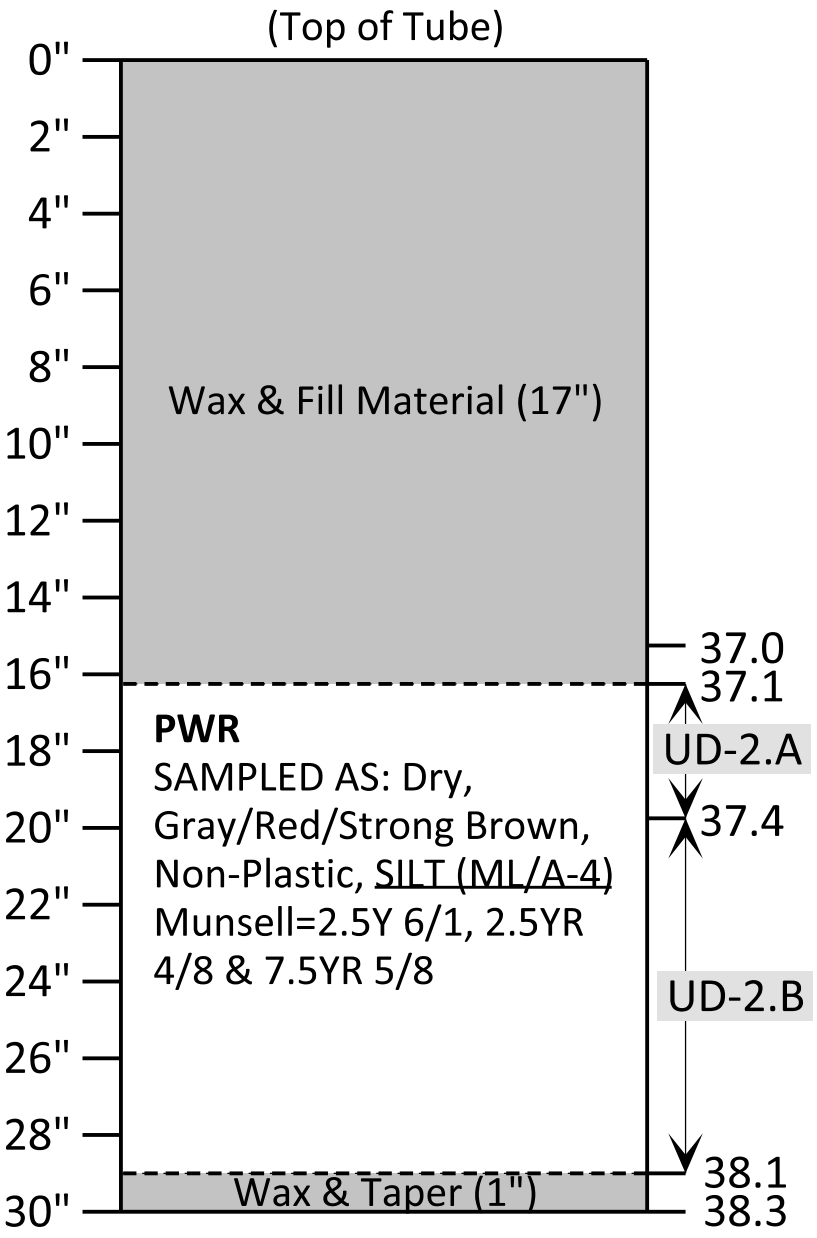
Shelby Tube UD-2



Prepared For: SCDOT

Project: Carolina Crossroads
I-20/26/126 Corridor Improvements

SCDOT Project ID: P027662

F&ME Project No.: G5662.01

Boring No.: AP-16

Sample Depth (feet): 37.0 - 38.3

Date Sampled: 5/4/2018

Date Pushed: 5/30/2018

Sample ID: 18-0854

Additional Comments:
The Shelby tube was advanced 15", and 13 3/4" of material was recovered. Sample UD-2.A had several large pieces of quartz gravel. One 6" sample was cut from sample UD-2.B. The sample was soaked in water, and immediately began falling apart when put in contact with the water. After four minutes, the sample had completely broken apart.

Boring No.: AP-17

Sample Depth (feet): 71.2 - 72.5

Date Sampled: 5/9/2018

Date Pushed: 5/25/2018

Sample ID: 18-0899

Additional Comments:
Shelby Tube was advanced 15" but recovered 26" of material. Soft material within the top 16" of tube, labeled as UD-2.A , UD-2.B & a portion of UD-2.C, appears to be cave-in material or material that was not recovered after sample UD-1 was attempted. Unconfined compression, grain size analysis, and Atterberg limits were not performed.

Sample Depth (feet): 6.0 - 8.5

Date Sampled: 5/22/2018

Date Pushed: 6/4/2018

Sample ID: 18-1007

Additional Comments:
The Shelby tube was advanced 30", and 27" of material was recovered. Approximately 1-1/2" of soil compression occured during extraction. Sample UD-1.B had a sizeable void when extracted from the tube. Samples UD-1.A & UD-1.C were used for triaxial shear. Sample UD-1.B was used for grain size analysis and Atterberg limits.

Laboratory Measurement of Soil Resistivity Using the Wenner Four-Electrode Method by ASTM G57 (Laboratory Measurement)

Boring ID	Sample ID	Depth, ft.	Sample Description	Electrical Resistivity, ohm-cm	Electrical Conductivity, $(ohm\text{-}cm)^{-1}$
B-6	---	6-8 ft	Moist, reddish yellow silty sand	101,936	9.81E-06

Notes: Test Equipment: Nilsson Model 400 Soil Resistance Meter, MC Miller Soil Box
Water added to sample to create a thick slurry prior to testing (saturated condition).
Electrical Conductivity is calculated as inverse of Electrical Resistivity (per ASTM G57)
Test conducted in standard laboratory atmosphere: 68-73 F

Project Name: I-20/26/126 CORRIDOR IMPROV.
Project Number: 307802
Lab Number: L1808774
Report Date: 03/21/18

Laboratory Measurement of Soil Resistivity Using the Wenner Four-Electrode Method by ASTM G57 (Laboratory Measurement)

Boring ID	Sample ID	Depth, ft.	Sample Description	Electrical Resistivity, ohm-cm	Electrical Conductivity, $(ohm\text{-}cm)^{-1}$
B-9	---	4-6 ft	Moist, red clay with sand	68,297	1.46E-05

Notes: Test Equipment: Nilsson Model 400 Soil Resistance Meter, MC Miller Soil Box
Water added to sample to create a thick slurry prior to testing (saturated condition).
Electrical Conductivity is calculated as inverse of Electrical Resistivity (per ASTM G57)
Test conducted in standard laboratory atmosphere: 68-73 F

Project Name: I-20/26/126 CORRIDOR IMPROVEME
Project Number: 307802
Lab Number: L1814569
Report Date: 05/01/18

Laboratory Measurement of Soil Resistivity Using the Wenner Four-Electrode Method by ASTM G57 (Laboratory Measurement)

Boring ID	Sample ID	Depth, ft.	Sample Description	Electrical Resistivity, ohm-cm	Electrical Conductivity, $(ohm\text{-}cm)^{-1}$
B-16	---	28.5-30 ft	Moist, dark yellowish brown sandy silt	34,658	2.89E-05

Notes: Test Equipment: Nilsson Model 400 Soil Resistance Meter, MC Miller Soil Box
Water added to sample to create a thick slurry prior to testing (saturated condition).
Electrical Conductivity is calculated as inverse of Electrical Resistivity (per ASTM G57)
Test conducted in standard laboratory atmosphere: 68-73 F

Project Name: I-20/26/126 CORRIDOR IMPROVE
Project Number: 307802
Lab Number: L1824882
Report Date: 07/10/18

Laboratory Measurement of Soil Resistivity Using the Wenner Four-Electrode Method by ASTM G57 (Laboratory Measurement)

Boring ID	Sample ID	Depth, ft.	Sample Description	Electrical Resistivity, ohm-cm	Electrical Conductivity, $(ohm\text{-}cm)^{-1}$
B-20	---	23.5-25 ft	Moist, light reddish brown sandy silt	93,781	1.07E-05

Notes: Test Equipment: Nilsson Model 400 Soil Resistance Meter, MC Miller Soil Box
Water added to sample to create a thick slurry prior to testing (saturated condition).
Electrical Conductivity is calculated as inverse of Electrical Resistivity (per ASTM G57)
Test conducted in standard laboratory atmosphere: 68-73 F

Client:	F&ME Consultants				
Project:	I-20/26/126 Corridor Improvements				
Location:	---			Project No:	GTX-307802
Boring ID:	---	Sample Type:	---	Tested By:	twh
Sample ID:	---	Test Date:	06/08/18	Checked By:	MCM
Depth :	---	Test Id:	295616		

pH of Soil by ASTM D4972

Boring ID	Sample ID	Depth	Visual Description	pH of Soil in Distilled Water	pH of Soil in Calcium Chloride
B-23	---	33.5-35 ft	Moist, light reddish brown sandy silt	4.4	3.5

Notes: Sample Preparation: screened through #10 sieve

Method A, pH meter used

Client:	F&ME Consultants
Project:	I-20/26/126 Corridor Improvement
Location:	---
GTX#:	307802
Test Date:	06/11/18
Tested By:	twh
Checked By:	emm

Laboratory Measurement of Soil Resistivity Using the Wenner Four-Electrode Method by ASTM G57 (Laboratory Measurement)

Boring ID	Sample ID	Depth, ft.	Sample Description	Electrical Resistivity, ohm-cm	Electrical Conductivity, $(ohm\text{-}cm)^{-1}$
B-23	---	33.5-35 ft	Moist, light reddish brown sandy silt	65,239	1.53E-05

Notes: Test Equipment: Nilsson Model 400 Soil Resistance Meter, MC Miller Soil Box
Water added to sample to create a thick slurry prior to testing (saturated condition).
Electrical Conductivity is calculated as inverse of Electrical Resistivity (per ASTM G57)
Test conducted in standard laboratory atmosphere: 68-73 F

Project Name: I-20/26/126 CORRIDOR IMPROVE
Project Number: 307802
Lab Number: L1824882
Report Date: 07/10/18

Laboratory Measurement of Soil Resistivity Using the Wenner Four-Electrode Method by ASTM G57 (Laboratory Measurement)

Boring ID	Sample ID	Depth, ft.	Sample Description	Electrical Resistivity, ohm-cm	Electrical Conductivity, $(ohm\text{-}cm)^{-1}$
B-27	---	23.5-25 ft	Moist, yellowish red sandy silt	45,871	2.18E-05

Notes: Test Equipment: Nilsson Model 400 Soil Resistance Meter, MC Miller Soil Box
Water added to sample to create a thick slurry prior to testing (saturated condition).
Electrical Conductivity is calculated as inverse of Electrical Resistivity (per ASTM G57)
Test conducted in standard laboratory atmosphere: 68-73 F

Project Name: I-20/26/126 CORRIDOR IMPROVE

SPECIFIC GRAVITY OF SOILS
(ASTM D854 / AASHTO T100)

Project Name:	I-20/26/126 Corridor Improvements	**Project No.:**	G5662.01
Sample Location:	AP-5	**Sample/Boring No.:**	18-1030
Description of Soil (Group Name & Symbol):	Sandy Lean CLAY (CL/A-6(10))	**Elevation/Depth of Sample:**	8.0' - 10.3'
% of Soils Passing #4 Sieve:		**Date Received:**	7/30/2018
Material Excluded:	**Yes**	X	**No**
Description of Excluded Material:			
Method:	**A**	X	**B**
Tested By:	William Pitts	**Date Tested:**	7/31/2018

Test No.	1			
Volume of Flask at 20° C	500ml			
Method of Air Removal	Boil			
Mass Flask + Water + Soil (Wb)	811.4			
Test Temperature ° C (Tx)	25			
Mass Flask + Water (Wa)	685.1			
Container No.	C			
Mass of Container + Oven Dry Soil	388.51			
Mass of Container	188.5			
Mass of Oven Dry Soil (Wo)	200.01			
Specific Gravity @ Test Temperature **Wo/[Wo+(Wa-Wb)]**	2.712			
Specific Gravity (SG) **K x Specific Gravity @ Test Temperature**	2.709			

$$K = \frac{\text{Related Density of Water @ Test Temperature}}{\text{Relative Density of Water @ 20° C}}$$

Average Specific Gravity of Soils = _____

Remarks: _____

One-Dimensional Consolidation by ASTM D2435 - Method B

SPECIFIC GRAVITY OF SOILS
(ASTM D854 / AASHTO T100)

Project Name:	I-20/26/126 Corridor Improvements	**Project No.:**	G5662.01
Sample Location:	AP-7	**Sample/Boring No.:**	18-1335
Description of Soil (Group Name & Symbol):	Sandy Lean CLAY (CL/A-6(7))	**Elevation/Depth of Sample:**	10.0' - 12.5'
% of Soils Passing #4 Sieve:		**Date Received:**	7/25/2018
Material Excluded:	**Yes**	X	**No**
Description of Excluded Material:			
Method:	**A**	X	**B**
Tested By:	William Pitts	**Date Tested:**	7/26/2018

Test No.	1			
Volume of Flask at 20° C	500ml			
Method of Air Removal	Boil			
Mass Flask + Water + Soil (Wb)	813.0			
Test Temperature ° C (Tx)	25			
Mass Flask + Water (Wa)	685.1			
Container No.	C			
Mass of Container + Oven Dry Soil	388.6			
Mass of Container	188.5			
Mass of Oven Dry Soil (Wo)	200.1			
Specific Gravity @ Test Temperature **Wo/[Wo+(Wa-Wb)]**	2.771			
Specific Gravity (SG) **K x Specific Gravity @ Test Temperature**	2.768			

$$K = \frac{\text{Related Density of Water @ Test Temperature}}{\text{Relative Density of Water @ 20° C}}$$

Average Specific Gravity of Soils = _____

Remarks: _____

CONSOLIDATED UNDRAINED TRIAXIAL TEST by AASHTO T297

	Saturation (Wet Method), %	72.3	80.7		
	Void Ratio	0.500	0.448		
Final	Moisture Content, %	17.5	15.2		
	Dry Density, pcf	114.	119.		
	Cross-Sectional Area (Method A), in²	6.279	6.281		
	Saturation, %	100.0	100.0		
	Void Ratio	0.469	0.408		
	Back Pressure, %	101.0	67.99		
Vertical Effective Consolidation Stress, psi		4.966	9.960		
Horizontal Effective Consolidation Stress, psi		4.990	9.991		
Vertical Strain after Consolidation, %		0.2111	0.5319		
Volumetric Strain after Consolidation, %		0.9729	2.177		
Time to 50% Consolidation, min		0.0000	0.0000		
Shear Strength, psi		3.395	8.682		
Strain at Failure, %		4.43	3.19		
Strain Rate, %/min		0.07500	0.07500		
Deviator Stress at Failure, psi		6.790	17.36		
Effective Minor Principal Stress at Failure, psi		2.013	4.628		
Effective Major Principal Stress at Failure, psi		8.803	21.99		
B-Value		0.95	0.95		

Notes:
- Before Shear Saturation set to 100% for phase calculation.
- Moisture Content determined by ASTM D2216.
- Deviator Stress includes membrane correction.
- Values for c and φ determined from best-fit straight line for the specific test conditions. Actual strength parameters may vary and should be determined by an engineer for site conditions.

SPECIFIC GRAVITY OF SOILS
(ASTM D854 / AASHTO T100)

Project Name:	I-20/26/126 Corridor Improvements	**Project No.:**	G5662.01
Sample Location:	AP-8	**Sample/Boring No.:**	18-1012
Description of Soil (Group Name & Symbol):	Sandy Lean CLAY (CL/A-7-6(13))	**Elevation/Depth of Sample:**	6' - 8.5'
% of Soils Passing #4 Sieve:		**Date Received:**	7/31/2018
Material Excluded:	**Yes**	X	**No**
Description of Excluded Material:			
Method:	**A**	X	**B**
Tested By:	William Pitts	**Date Tested:**	8/1/2018

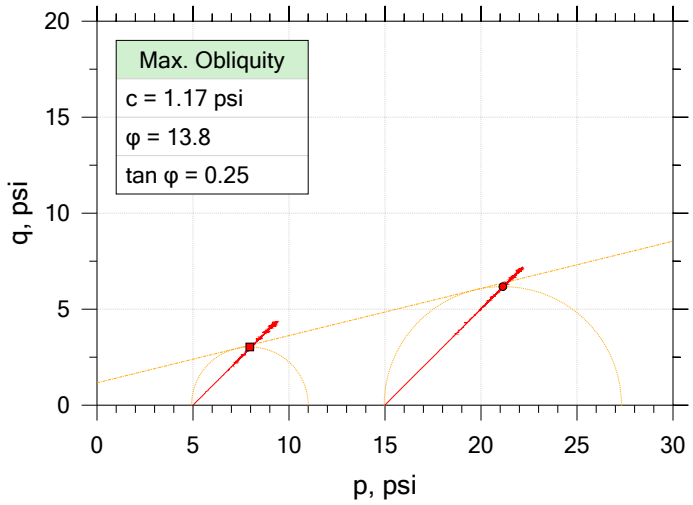
Test No.	1			
Volume of Flask at 20° C	500ml			
Method of Air Removal	Boil			
Mass Flask + Water + Soil (Wb)	811.3			
Test Temperature ° C (Tx)	25			
Mass Flask + Water (Wa)	686.5			
Container No.	E			
Mass of Container + Oven Dry Soil	389.52			
Mass of Container	189.5			
Mass of Oven Dry Soil (Wo)	200.02			
Specific Gravity @ Test Temperature **Wo/[Wo+(Wa-Wb)]**	2.657			
Specific Gravity (SG) **K x Specific Gravity @ Test Temperature**	2.654			

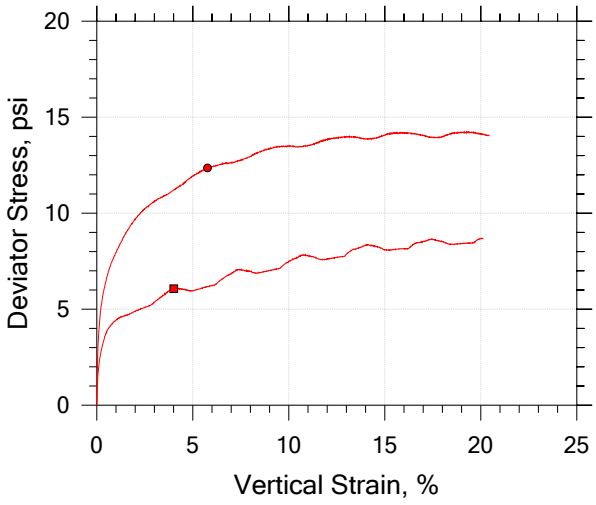
$$K = \frac{\text{Related Density of Water @ Test Temperature}}{\text{Relative Density of Water @ 20° C}}$$

Average Specific Gravity of Soils = _____

Remarks: _____

CONSOLIDATED UNDRAINED TRIAXIAL TEST by AASHTO T297





Symbol		■	●

Initial	Height, in	5.950	5.885		
	Diameter, in	2.866	2.856		
	Moisture Content (from Cuttings), %	16.8	22.7		
	Dry Density, pcf	97.3	102.		
	Saturation (Wet Method), %	62.5	94.4		
	Void Ratio	0.719	0.644		
Final	Moisture Content, %	24.3	21.9		
	Dry Density, pcf	101.	105.		
	Cross-Sectional Area (Method A), in²	6.272	6.249		
	Saturation, %	100.0	100.0		
	Void Ratio	0.651	0.587		
	Back Pressure, %	79.99	101.0		
Vertical Effective Consolidation Stress, psi		4.952	14.94		
Horizontal Effective Consolidation Stress, psi		4.999	15.00		
Vertical Strain after Consolidation, %		0.8016	0.9739		
Volumetric Strain after Consolidation, %		2.667	3.219		
Time to 50% Consolidation, min		0.0000	0.0000		
Shear Strength, psi		2.922	11.08		
Strain at Failure, %		11.8	3.48		
Strain Rate, %/min		0.07500	0.07500		
Deviator Stress at Failure, psi		5.845	22.15		
Effective Minor Principal Stress at Failure, psi		2.271	7.724		
Effective Major Principal Stress at Failure, psi		8.116	29.87		
B-Value		0.95	0.95		

Notes:
- Before Shear Saturation set to 100% for phase calculation.
- Moisture Content determined by ASTM D2216.
- Deviator Stress includes membrane correction.
- Values for c and φ determined from best-fit straight line for the specific test conditions. Actual strength parameters may vary and should be determined by an engineer for site conditions.

Project ID P027662, Lexington and Richland Counties, South Carolina
S&ME Project No. 1461-16-047

Dear Mr. Kinard:

The purpose of this report is to convey geotechnical subsurface data to HDR Engineering, Inc. (HDR) and the South Carolina Department of Transportation (SCDOT) for use by a contractor in a future design-build project. Test locations are widely spaced and therefore only fulfill a portion of the subsurface exploration required by SCDOT for Bridge and Roadway Geotechnical Engineering Reports. Our services were performed in general accordance with the Sub-Consultant Agreement between HDR and S&ME, Inc. dated August 17, 2016, including subcontract modification dated January 24, 2018, and portions of the SCDOT *Geotechnical Design Manual* (GDM), 2010 version.

S&ME appreciates this opportunity to work with you on this important project. Please contact us at (803) 561-9024 if you have any questions or need any additional information regarding this report.

Sincerely,

S&ME, Inc.

1.0 Project Description

The proposed construction for this project includes the improvement of the existing I-20, I-26, and I-126 corridor, including new bridges, overpasses, interchanges, ramps, and widening. The associated roadway realignment will also be included. The project includes approximately four miles of I-20, nine miles of I-26, and one mile of I-126, located in Lexington and Richland Counties in the Columbia, South Carolina metropolitan area. The approximate project location is shown on the *Overall Site Plan*, provided as Figure 1 in Appendix I.

2.0 Objective

The objective of our services was to explore the subsurface conditions along the I-20, I-26, and I-126 corridor as they pertain to the proposed improvements, and in conjunction with field and laboratory testing, to provide limited geotechnical data.

3.0 Scope of Work

Representatives of S&ME were present for on-site field activities between January 4, 2018, and June 6, 2018, to conduct the following testing:

- 129 total Standard Penetration Test (SPT) borings with wireline rock coring in applicable borings;
- Downhole seismic testing at three boring locations;
- 30 bulk samples at selected pavement and embankment boring locations;
- 20 undisturbed samples (Shelby tubes) obtained at selected bridge, embankment, and wall boring locations;
- Ten Cone Penetrometer (CPT) soundings;
- Two Marchetti Dilatometer Test (DMT) soundings

Testing was conducted at or near the proposed locations provided in the *Phase 2B Subsurface Exploration Plan*, by S&ME, Inc., dated January 10, 2018. Testing locations were modified as necessary due to utilities, terrain, to minimize traffic control impacts, and to facilitate safe working conditions.

Additionally, laboratory testing was performed on disturbed and undisturbed soil samples, bulk soil samples, and rock core samples collected in the field. The Laboratory testing program is described in more detail in the following sections.

4.0 Test Locations

The testing locations were initially established in the field by representatives of S&ME using our hand-held sub-meter GPS unit. As-built survey of the testing locations was performed by Glenn Associates Surveying, Inc., under subcontract to S&ME. The approximate testing locations are shown on the *Test Location Plan,* included as Figures 2 through 11 in Appendix I. A summary of testing locations, depths and elevations are presented in Table 1, *Test Location Summary*, in Appendix II. Surveyed coordinates are tabulated in decimal degree latitude and longitude

coordinates. The station and offset presented for each test location was referenced to proposed alignments shown in the electronic drawing file, *RA1_STV_Alignments.dgn*, dated 2/7/2018, provided by HDR, Inc. Where applicable, the associated Site number for each test location is provided as referenced from the structures numbering scheme, provided in *RA1 Structures Numbering – 2-12-18.pdf*, provided by HDR, Inc.

5.0 Exploration Procedures

As previously mentioned, the subsurface exploration of this project included SPT borings, wireline rock coring, downhole seismic testing, bulk sampling, undisturbed sampling, CPT soundings, and DMT soundings. The following sections summarize the field test procedures. The field testing data are organized into appendices of this report as follows:

- Appendix III - Soil and Rock Core Boring Records
- Appendix IV – Rock Core Box Photographs
- Appendix V – CPT Sounding Logs
- Appendix VI – DMT Sounding Data
- Appendix VII – Downhole Seismic Data

5.1 Traffic Control

Traffic control was required for a majority of the borings performed. In general, traffic control consisted of nighttime lane closures on Interstate and multi-lane primary and secondary routes. Daytime Interstate shoulder closures, as well as lane closures with flagging operations on primary and secondary routes were also utilized. Traffic control was performed by Area Wide Protective, under subcontract to S&ME, Inc. Traffic control configurations and work hours were in accordance with applicable SCDOT standard drawings and hourly lane closure restrictions.

5.2 Site Clearing

Several test locations for the proposed alignments were located in wooded areas off the existing roadways where mechanized clearing was necessary to provide access for our drilling equipment. The clearing was performed by Carolina Brushcutters, Inc. under subcontract to S&ME, using a skid steer-mounted forestry grinder and operator to create access pathways and drill pads at the boring locations. Trails of approximately 12 to 15 feet wide were cleared with trees chipped in-place. At the boring location itself, an approximate 30x30 foot work area was cleared as necessary to facilitate operations. No attempt was made to stack or remove downed trees from the site. Care was taken to limit site disturbance during this process.

5.3 Standard Penetration Test (SPT) Borings

One hundred and twenty nine (129) soil test borings with SPT sampling were performed for this project between the dates of January 4, 2018, and April 13, 2018, using three drill rigs as follows:

Table 5-1 – S&ME Drilling Equipment Summary

Rig Make/Model	Serial No.	Carrier Type	Average SPT Energy Transfer Ratio (ETR), %
Diedrich D-50	382	ATV	86.5
CME-55	328245	Truck Mounted	84.1
CME-750	322938	ATV	86.0

Bridge (B-series), Retaining Wall (W-series), Embankment (RW-series), and Seismic (DH-series) SPT borings were advanced using mud rotary drilling techniques. Pavement (P-series) SPT borings were advanced using hollow stem auger drilling techniques. Soil sampling and penetration testing were performed in general accordance with ASTM D1586 *Standard Test Method for Penetration Test and Split Barrel Sampling of Soils*. The borings were extended to the planned termination depths, auger or drill bit refusal depths, followed by wireline rock coring, where applicable, at seismic, bridge and wall boring locations. A summary of the borings performed is provided in the table below.

Table 5-2 – Boring Summary

Purpose	Boring No.	Quantity
Seismic Borings	DH-4 through DH-6	3
Bridge Borings	B-29 through B-62	35
Retaining Wall Borings	W-18, W-19, W-22 through W-25, and W-27 through W-32	12
Embankment Borings	RW-35 through RW-43	9
Pavement Borings (1)	P-1 through P-45 and P-47 through P-71	70

(1) The P-Series borings were performed at their designated locations within the paved shoulder area located outside of the travel lanes along I-20, I-26, and I-126.

The originally planned pavement boring P-46 was deleted from the scope due to the proximity of bridge boring B-47 to this location. Boring B-47 was performed in the paved shoulder to provide pavement information at this location. In addition, boring W-26, which was originally planned under the Phase 2B scope of work, was shifted to the Phase 2A scope of work and will be reported by F&ME under separate cover.

Pavement coring was performed at the Pavement Boring locations and other boring locations within the roadway or shoulder. The pavement coring was performed using a 4 to 8-inch outer diameter, diamond-tipped, core barrel attached to the drill rig. The cores were performed to obtain a sample for thickness measurements and evaluation, and to provide a clean cut through the existing pavements to allow access to the underlying materials. A photograph log of recovered existing pavement cores can be found in Appendix XIV.

Soil sampling and penetration testing were performed in general accordance with ASTM D1586 *Standard Test Method for Penetration Test and Split Barrel Sampling of Soils*. SPT was performed in each boring continuously in the upper 10 feet, and at approximate 5-foot intervals thereafter. The split-barrel sampler was opened at the drill

site and sloughed material was identified and separated from the recovered sample. The recovered sample was visually described and classified by S&ME's rig geologist or engineer. A selected portion of the sample was placed in a glass jar with a moisture-proof lid. Where materials changed over the sample drive length, a sample of each material was retained. The sample jars were labeled, placed in cardboard boxes, and transported to the S&ME Columbia Office at the end of each work day.

Water level measurements were attempted immediately after completion of drilling and, where feasible, were repeated after a period of 24 hours. We note that due to the use of drilling fluid additives, the water level readings recorded in the soil borings may not accurately reflect the ground water conditions at the site. Stabilized ground water readings were conducted in general accordance with ASTM D4750 *Standard Test Method for Determining Subsurface Liquid Levels in a Borehole or Monitoring Well (Observation Well)*.

After ground water measurements were complete, borings conducted within existing pavements were abandoned with Portland cement/bentonite grout. The boreholes performed outside the existing roadway and existing paved shoulder were backfilled with drill cuttings and/or bentonite chips up to an approximate depth of 10 ft. The upper 10 feet was then filled with Portland cement/bentonite grout. The pavement section of boreholes within the existing roadway and paved shoulders were patched with commercially available bagged asphalt, as necessary. The concrete section for borings conducted through existing bridge decks was patched with Repcon 928, a high performance, high strength, non-shrink, fast-setting concrete.

SPT hammer energy measurements with a Pile Driving Analyzer (PDA) were previously performed by S&ME at off-site locations for the drill rigs used on the project in general accordance with ASTM D4633. The SPT Energy test results are provided in Appendix XIII. The N-values indicated on the logs are field values and were not corrected for overburden stress, rod length, borehole diameter or hammer efficiency. The hammer energy ratios are reported on the individual soil test boring records in Appendix III.

5.4 Wireline Rock Coring

At applicable seismic, bridge, and wall boring locations, wireline rock coring was performed to explore the refusal materials in general accordance with ASTM D2113. Rock coring was performed in the majority of the borings using an NQ-size core barrel and wireline retrieval system. A larger, HQ-sized core barrel was utilized for seismic borings DH-4 through DH-6 to facilitate installation of PVC casing for downhole testing as described below. The recovered rock cores were visually logged by the S&ME rig geologist or engineer. The rock core samples were placed in wooden core boxes labeled with appropriate project information. Photographs were taken of each completed core box prior to any core being removed for laboratory testing. Completed core boxes were transported to the S&ME Columbia Office at the end of each work day. The rock cores were preserved, handled and transported in general accordance with ASTM D5079-08.

5.5 Bulk Samples

Thirty (30) bulk samples were obtained from the site at selected pavement and embankment borings. The representative bulk samples of near-surface soils were obtained by randomly taking shovel loads of the cuttings brought to the surface by the hollow stem augers until approximately two, 5-gallon buckets of materials was obtained at each location. The buckets were sealed with lids and marked with appropriate project information.

5.6 Undisturbed Samples (Shelby Tubes)

Undisturbed samples (Shelby tubes) were obtained in companion off-set borings adjacent to eight selected bridge, embankment, and wall boring locations. Twenty (20) relatively undisturbed (UD) samples, or Shelby Tubes, were performed between March 26, 2018, and April 3, 2018, in general accordance with ASTM D1587 *Standard Practice for Thin-Walled Tube Sampling of Fine Grained Soils for Geotechnical Purposes*. Shelby tube sample depths were selected by S&ME upon review of the SPT logs, and assigned accordingly.

Shelby Tubes provide sufficiently intact samples for laboratory testing. Samples were obtained by pushing a 3-inch outer diameter, 16-guage, steel tube into the soil at the desired sampling intervals in mud-rotary drilled borehole adjacent to the original SPT location. The tube, together with the encased soil, was carefully removed from the ground and length of the recovered soil measured. The ends of the tube were sealed with microcrystalline wax and labeled with applicable project information before being transported to our laboratory. Shelby tube samples were transported and stored in general accordance with ASTM D4220-14 for Group C samples.

5.7 Shear Wave Velocity Test by Down Hole Method

Upon completion of drilling activities for seismic borings DH-4, DH-5, and DH-6, flush-threaded schedule 40 PVC casing was installed and the annulus grouted in place for down-hole shear wave testing activities using a cement/bentonite grout mixture to support shear wave velocity testing.

Shear wave velocity measurements were performed between January 17 and January 30th, 2017, in cased boreholes DH-4, DH-5, and DH-6, using downhole methods in general accordance with ASTM D7400 *Standard Test Methods for Downhole Seismic Testing*. The testing at the site was conducted using a Geometrics ES3000 seismograph and a 14 Hz downhole triaxial geophone. Measurements were taken at depth intervals of approximately 3 feet. Shear and compression waves were generated by a 16-pound sledgehammer striking a wooden plank. The analysis was conducted using the OYO Corporation's SeisImager/SW software (Pickwin). The Shear Wave Velocity Profile and tabulated data are attached in Appendix VII. After completion of down-hole shear wave velocity testing, the PVC casing was abandoned in place by tremie grouting the inside of the casing with a cement/bentonite slurry approximately flush with the ground surface.

5.8 Cone Penetrometer (CPT) Soundings

Ten (10) CPT soundings were performed between May 21, 2018, and June 6, 2018, using both a truck-mounted and an ATV-mounted drill rig. Locations of CPT soundings were selected by S&ME upon review of the SPT logs, and assigned accordingly. CPT soundings consist of a conical pointed penetrometer which is hydraulically pushed into the soil at a slow, measured rate. Procedures for measurement of the tip resistance and side friction resistance to push generally follow those described by ASTM D-5778 *Standard Test Method for Performing Electronic Friction Cone and Piezocone Penetration Testing of Soils*. The Cone Penetration Test records are provided in Appendix V. The calibration records for cone serial nos. 4444.177 and 4433.102, used to perform the soundings for this project, is presented in Appendix V. The calibrations were performed by the cone manufacturer, Vertek, on April 11, 2018 and July 7, 2017, respectively.

5.9 Marchetti Dilatometer Test (DMT) Soundings

Two (2) DMT soundings were performed between June 5 and 6, 2018, using a truck-mounted CPT rig. Locations of DMT soundings were selected by S&ME upon review of the SPT logs, and assigned accordingly. The DMT soundings were performed in general accordance with procedures described in FHWA Publication SA-91-044, *The Flat Dilatometer Test*. The Dilatometer Test records are provided in Appendix VI.

6.0 Classification of Recovered Soil and Rock Core Samples

Recovered split spoon and bulk samples were initially classified in general accordance with ASTM D2488 *Standard Practice for Description and Identification of Soils (Visual-Manual Method)*. After laboratory testing was completed, provisional field classifications were revised as necessary to provide a soil description that generally follows the terminology given by ASTM D2487 *Standard Practice for Classification of Soils for Engineering Purposes (Unified Soil Classification System)* and AASHTO M145 *Recommended Practice for Classification of Soils and Soil-Aggregate Mixtures for Highway Construction Purposes*.

Recovered rock core samples were reviewed and classified in general accordance with the SCDOT GDM Chapter 6, Section 6.3. Upon return to our laboratory, the rock core samples were reviewed and classified by a Professional Geologist (PG). Recovered core examined in the laboratory were assigned descriptive terms using tables 6-13 through 6-19 of the SCDOT Geotechnical Design Manual (GDM) where applicable to the rock type. Foliation within the rock was judged as very thick using Table 6-15. Rock lithologic descriptions, and applicable descriptive information are included on the Soil Test Boring Records in Appendix III. Discontinuities in the recovered cores were evaluated using the terminology in GDM Table 6-21. The results of the discontinuity examination are tabulated in the *Rock Core Discontinuity Worksheets* for each cored borehole, included in Appendix III. After logging, selected sections of rock core were removed and prepared for laboratory compressive strength testing.

After laboratory testing was completed, the Rock Mass Rating (RMR) was computed in general accordance with the SCDOT GDM and Section 10 of the 2014 AASHTO LRFD *Bridge Design Specifications*. Additionally, the Geological Strength Index (GSI) was determined in general accordance with the 2014 AASHTO LRFD *Bridge Design Specifications*. A summary of the Rock Core Testing is provided in Table 8, Appendix II of this report.

Interpreted subsurface conditions encountered by the borings are shown on the Soil and Rock Core Boring records in Appendix III. These records represent our interpretation of the subsurface conditions based on the test data. Stratification lines on the boring records represent approximate boundaries between soil and rock types; however, the actual transition may be gradual and the thicknesses of the strata will vary across the site. The soil and rock samples will be retained at our laboratory for a period of seven years, or until substructure completion, whichever comes first.

7.0 Laboratory Tests

Index property testing consisting of Atterberg limits, particle-size distribution, percent finer #200 sieve, and natural moisture content tests were performed on split-spoon soil samples to assist in classifying the soils. Additionally, organic content and corrosion series (pH, chloride, sulfate, and resistivity) testing were performed on

selected split-spoon samples. Atterberg limits, particle-size distribution, natural moisture content, standard proctor moisture-density, California bearing ratio (CBR), and ignition loss testing were performed on bulk soil samples. Atterberg limits, particle-size distribution, natural moisture content, one-dimensional consolidation, and consolidated undrained triaxial shear testing were performed on undisturbed samples. Uniaxial compressive strength testing was performed on selected rock core specimen. Tables summarizing the laboratory test results are provided in Appendix II as follows:

- Table 2: Split Spoon Samples – Laboratory Classification Testing Summary
- Table 3: Bulk Samples – Laboratory Classification & Ignition Loss Testing Summary
- Table 4: Bulk Samples – Standard Proctor and CBR Testing Summary
- Table 5: Corrosion Series Testing Summary
- Table 6: Undisturbed Samples – Consolidation Testing Summary
- Table 7: Undisturbed Samples – Consolidated Undrained Triaxial Testing Summary
- Table 8: Rock Core Testing Summary

Testing was performed in general accordance with ASTM, AASHTO, or SC state test procedures as follows:

- Atterberg limits – ASTM D4318 / AASHTO T89/90
- Particle-size distribution – ASTM D422 / AASHTO T88
- Percent-finer 200 sieve – ASTM D1140 / AASHTO T11
- Natural moisture content – ASTM D2216 / AASHTO T265
- Organic content – ASTM D2974 / AASHTO T267
- Corrosion Series:
  - pH – ASTM G51 / AASHTO T289
  - Chloride – AASHTO T291
  - Sulfate – ASTM C1580 / AASHTO T290
  - Resistivity – AASHTO T288
- Standard proctor moisture-density – ASTM D698 / AASHTO T99
- California Bearing Ratio (CBR) – ASTM D1883 / AASHTO T193
- Ignition loss – SC-T-36
- One-dimensional consolidation – ASTM D2435
- Consolidated undrained triaxial shear – ASTM D4767
- Compressive strength of rock cores – ASTM D7012 (Methods C&D)

The individual laboratory test data sheets are organized into appendices of this report as summarized below:

- Appendix VIII: Laboratory Test Data Sheets – Split Spoon Samples
- Appendix IX: Laboratory Test Data Sheets – Bulk Samples
- Appendix X: Laboratory Test Data Sheets – Corrosion Series Testing
- Appendix XI: Laboratory Test Data Sheets – Undisturbed Samples
- Appendix XII: Laboratory Test Data Sheets – Rock Core Samples

8.0 Shear Wave Velocity Test by Down Hole Method

Velocity measurements were obtained to depths of approximately 117 feet below the existing ground surface at Seismic Borings DH-4, DH-5, and DH-6. A summary of the testing is provided in the table below. In addition, the plots of shear wave velocity as a function of depth are provided in Appendix VII.

Table 9-1 – Shear Wave Velocity Summary

Boring No.	Total Test Depth (ft.)	Weighted Average Shear Wave Velocity (ft./s)	Weighted Average Depth Interval (ft.)
DH-4	117.1	3,232	6.1 to 105.1
DH-5	117.3	2,775	6.3 to 105.3
DH-6	117.8	3,207	6.8 to 105.8

9.0 Closing and Qualification of Report

This data report has been prepared in general accordance with procedures in SCDOT GDM Chapter 21 and with generally applicable standards of our practice in this geographic area at the time this report was prepared. No other warranty, express or implied, is made. The Geotechnical Engineer of Record for the project must review the data submitted in this report and develop their own interpretation of the testing results as they apply to design.

We relied on project information given to us to develop our exploration program. If project information described in this report is not accurate, or if it changes during project development, we should be notified of the changes.

This report presents data from a limited field exploration program. Subsurface conditions will vary widely between explored areas. Some variations may not become evident until construction. If conditions are encountered which appear different than those described in our report, we should be notified. This report should not be construed to represent subsurface conditions for the entire site.

Unless specifically noted otherwise, our field exploration program did not include an assessment of regulatory compliance, environmental conditions or pollutants or presence of any biological materials (mold, fungi, bacteria). If there is a concern about these items, other studies should be performed.

Concrete

Topsoil

Gravel

Sand

Silt

Clay

Organic

Silty Sand

Clayey Sand

Sandy Silt

Clayey Silt

Sandy Clay

Silty Clay

Partially Weathered Rock

Cored Rock

WATER LEVELS

(Shown in Water Level Column)

▽ = Water Level At Termination of Boring
▼ = Water Level Taken After 24 Hours
◄ = Loss of Drilling Water
HC = Hole Cave

CONSISTENCY OF COHESIVE SOILS

CONSISTENCY	STD. PENETRATION RESISTANCE BLOWS/FOOT
Very Soft	0 to 2
Soft	3 to 4
Firm	5 to 8
Stiff	9 to 15
Very Stiff	16 to 30
Hard	31 to 50
Very Hard	Over 50

RELATIVE DENSITY OF COHESIONLESS SOILS

RELATIVE DENSITY	STD. PENETRATION RESISTANCE BLOWS/FOOT
Very Loose	0 to 4
Loose	5 to 10
Medium Dense	11 to 30
Dense	31 to 50
Very Dense	Over 50

TERMS

Standard Penetration Resistance - The Number of Blows of 140 lb. Hammer Falling 30 in. Required to Drive 1.4 in. I.D. Split Spoon Sampler 1 Foot. As Specified in ASTM D-1586.

REC - Total Length of Rock Recovered in the Core Barrel Divided by the Total Length of the Core Run Times 100%.

RQD - Total Length of Sound Rock Segments Recovered that are Longer Than or Equal to 4" (mechanical breaks excluded) Divided by the Total Length of the Core Run Times 100%.

SCDOT Soil Test Boring Log Descriptors

ROCK WEATHERING / ALTERATION

Description	Recognition
Residual Soil	Original minerals of rock have been entirely decomposed to secondary minerals, and original rock fabric is not apparent; material can be easily broken by hand
Completely Weathered / Altered	Original minerals of rock have been almost entirely decomposed to secondary minerals, although the original fabric may be intact; material can be granulated by hand
Highly Weathered / Altered	More than half of the rock is decomposed; rock is weakened so that a minimum 1-7/8 inch diameter sample can be easily broken readily by hand across rock fabric
Moderately Weathered / Altered	Rock is discolored and noticeably weakened, but less than half is decomposed; a minimum 1-7/8 inch diameter sample cannot be broken readily by hand across rock fabric
Slightly Weathered / Altered	Rock is slightly discolored, but not noticeably lower in strength than fresh rock
Fresh	Rock shows no discoloration, loss of strength, or other effect of weathering / alteration

ROCK STRENGTH

Description	Recognition	Approximately Uniaxial Compressive Strength (psi)
Extremely Weak Rock	Can be indented by thumbnail	35 – 150
Very Weak Rock	Can be peeled by pocket knife	150 –700
Weak Rock	Can be peeled with difficulty by pocket knife	700 – 3,500
Medium Strong Rock	Can be indented 3/16 inch with sharp end of pick	3,500 – 7,200
Strong Rock	Requires one hammer blow to fracture	7,200 – 14,500
Very Strong Rock	Requires many hammer blows to fracture	14,500 – 35,000
Extremely Strong Rock	Can only be chipped with hammer blows	> 35,000

DISCONTINUITY DESCRIPTORS

[k] - Dip of fracture surface measured relative to horizontal with bearing and direction

[l] Discontinuity Type
- F - Fault
- J - Joint
- Sh - Shear
- Fo - Foliation
- V - Vein
- B - Bedding

[m] Discontinuity Width (millimeters)
- W - Wide (12.5 – 50)
- MW - Moderately Wide (2.5 – 12.5)
- N - Narrow (1.25 – 2.5)
- VN - Very Narrow (< 1.25)
- T - Tight (0)

[n] Amount of Infilling
- Su - Surface Stain
- Sp - Spotty
- Pa - Partially Filled
- Fi - Filled
- No - None

[o] Type of Infilling
- Cl - Clay
- Ca - Calcite
- Ch - Chloride
- Fe - Iron Oxide
- Gy - Gypsum/Talc
- H - Healed
- No - None
- Py - Pyrite
- Qz - Quartz
- Sd - Sand

[p] Surface Shape of Joint
- Wa - Wavy
- Pl - Planar
- St - Stepped
- Ir - Irregular

[q] Discontinuity Spacing (feet)
- EW Extremely Wide (> 65)
- W Wide (22 – 65)
- M Moderate (7.5 – 22)
- C Close (2 – 7.5)
- VC Very Close (< 2)

[r] Roughness of Surface
- Slk - Slickensided (surface has smooth, glassy finish with visual evidence of striations)
- S - Smooth (surface appears smooth and feels so to the touch)
- SR - Slightly Rough (asperities on the discontinuity surfaces are distinguishable and can be felt)
- R - Rough (some ridges and side-angle steps are evident; asperities are clearly visible, and discontinuity surface feels very abrasive
- VR - Very Rough (near-vertical steps and ridges occur on the discontinuity surface)
